VISION

The vision of the journals is to provide an academic platform to scholars all over the world to publish their novel, original, empirical and high quality research work. It propose to encourage research relating to latest trends and practices in international business, finance, banking, service marketing, human resource management, corporate governance, social responsibility and emerging paradigms in allied areas of management. It intends to reach the researcher's with plethora of knowledge to generate a pool of research content and propose problem solving models to address the current and emerging issues at the national and international level. Further, it aims to share and disseminate the empirical research findings with academia, industry, policy makers, and consultants with an approach to incorporate the research recommendations for the benefit of one and all.

ABSTRACT

Deep learning techniques, particularly convolutional networks, have quickly risen to prominence as the preferred approach for interpreting medical pictures. This article highlights nearly 300 contributions to the area, the most of which were published during the past year, and covers the main deep learning principles relevant to medical picture analysis. We look at how deep learning may be used for picture categorization, object recognition, segmentation, registration, and other applications. Studies in the following areas are summarized briefly: neuro, retinal, pulmonary, digital pathology, breast, cardiac, abdominal, and musculoskeletal. We conclude with a review of the present state of the art, a critical evaluation of outstanding problems, and future research prospects. In an era of medical big data, the benefit of deep learning is that important hierarchical connections within the data may be found algorithmically rather than laboriously hand-crafting features. We go through the fundamentals of medical image classification, localization, detection, segmentation, and registration, as well as their applications.We wrap off by talking about research roadblocks, new patterns, and potential future paths.

KEYWORDS:*Convolutional Neural Networks, Deep Learning, Dimensional Medical Image Analysis, Machine Learning.*

1. INTRODUCTION

Researchers began developing automated analysis tools as soon as it was feasible to scan and load medical pictures onto a computer. From the 1970s through the 1990s, medical image analysis was accomplished by combining low-level pixel processing (edge and line detector filters, region expanding) with mathematical modeling (fitting lines, circles, and ellipses) to create compound rule-based systems that performed specific tasks. Expert systems include numerous if-then-else statements, which were popular in artificial intelligence around the same time period. GOFAI (good oldfashioned artificial intelligence) was a term used to characterize

expert systems that were fragile and comparable to rule-based image processing systems.Guided methods, in which training data is used to build a system, were more prominent in medical image analysis towards the end of the 1990s[1]. Active shape models, atlas techniques, and the idea of feature extraction and the usage of statistical classifiers are all examples. This pattern recognition or machine learning approach is still widely used, and many commercially available medical image analysis systems are based on it[2]. As a result, we've witnessed a transition from systems that are entirely developed by humans to systems that are taught by computers utilizing example data and extracted feature vectors. In the high-dimensional feature space, computer algorithms establish the best decision boundary. The extraction of discriminant characteristics from pictures is a critical step in the construction of such systems. This procedure is still carried out by human researchers, and as a result, systems with handmade characteristics are referred to. Allowing computers to learn the characteristics that best describe the data for the issue at hand is a natural next step. Many deep learning techniques are based on this concept: models (networks) with many layers that convert input data (e.g. pictures) into outputs (e.g. illness present/absent) while learning higher level characteristics. Convolutional neural networks have proven to be the most effective kind of image processing model to date (CNNs)[3]. CNNs have several layers that use tiny convolution filters to modify their input. CNNs have been studied since the late 1970s , and they were first used in medical image analysis .In LeNet, they saw their first successful real-world application for hand-written digit recognition. Despite these early successes, the use of CNNs did not gain traction until new techniques for efficiently training deep networks were developed, as well as advances in core computing systems. The contribution of to the ImageNet challenge in December 2012 was the turning point[3]. AlexNet, the proposed CNN, won the competition by a large margin. Using related but deeper architectures, more progress was made in subsequent years. Deep convolutional networks have supplanted other techniques in computer vision. These significant developments have been noticed by the medical image analysis community. The shift from systems that utilize handmade features to systems that learn features from data, on the other hand, has been slow. Many different techniques for learning features were popular before AlexNet's breakthrough. give a comprehensive overview of various methods. Principal component analysis, image patch clustering, dictionary approaches, and many others are among them. Only at the end of their review, in a section titled Global training of deep models, introduce CNNs that are trained end-to-end. We concentrate only on such deep models in our study, and we leave out more conventional feature learning methods that have been used on medical pictures[4].

1.1 History of medical image analysis:

The rule-based, expert systems were developed as a result of the symbolic AI paradigm of the 1970s. Shurtleff's MYCIN system, which suggested different antibiotic therapy regimens for patients, was an early implementation in medicine. Parallel to these advancements, AI algorithms transitioned from heuristic-based techniques to manual, handcrafted feature extraction techniques, and finally to supervised learning techniques. Although unsupervised machine learning methods are being investigated, the majority of the algorithms published in the literature between 2015 and 2017 used supervised learning methods, such as Convolutional Neural Networks (CNN). Apart from the availability of large labelled data sets, hardware advancements in Graphical Processing Units (GPUs) have also improved CNN performance, resulting in their widespread use in medical image analysis. The first artificial neuron was described by McCulloch and Pitts in 1943, and the perceptron was proposed by Rosenblatt in 1958. An artificial neural network (ANN) is a layer of connected perceptron's that links inputs and outputs, and deep neural networks are multiple layers of ANNs. A deep neural channel's benefit is its capacity to learn important low-level characteristics (such as lines or edges) and combine them with higher-level features (such as shapes) in future layers. This is how the visual cortices

of mammals and humans are thought to process visual information and recognize objects. CNNs may have their roots in Fukushima's Neocognitron concept from 1982, but it was who formalized CNNs and errorsbackpropagation to successfully perform the automatic recognition of handwritten digits. After won the 2012 Imagenet Large Scale Visual Recognition Challenge (ILSVRC) using a CNN that had a 15% error rate, CNNs were widely used in image recognition. The runner-up had a mistake rate of nearly twice that of the winner, at 26%. The use of Rectified Linear Unit (RELU) functions in CNNs, data augmentation, and dropout were all introduced by and are still used in CNNs today. Since then, CNNs have been the most widely used architecture in every ILSVRC competition, even surpassing human performance in image recognition in 2015. As a result, the number of research papers published on CNN design and applications has increased dramatically, making CNNs the dominating architecture in medical image processing[3].

1.1 CONVOLUTIONAL NEURAL NETWORKS

The 2-dimensional and 3-dimensional architecture of the organ being examined are both important in determining what is normal and what is pathological. CNNs are well-suited to conduct image identification tasks because they retain these local spatial connections. CNNs have been used for image classification, localization, detection, segmentation, and registration, among other things. Due to its unique feature of maintaining local picture connections while conducting dimensionality reduction, CNNs are the most common machine learning method in image identification and visual learning applications[5]. This captures key feature connections in an image (such as how pixels on an edge combine to create a line) while also reducing the amount of parameters the algorithm must calculate, resulting in increased computational efficiency. CNNs can process both 2-dimensional and 3-dimensional pictures with minimal changes as inputs. Because certain modalities, such as X-rays, are 2-dimensional, while others, such as CT or MRI scans, are 3-dimensional volumes, this is a beneficial benefit when developing a system for hospital usage. CNNs and Recurrent Neural Networks (RNNs) are supervised machine learning algorithms that need a lot of training data. Medical image analysis has also been explored using unsupervised learning methods. Autoencoders, Restricted Boltzmann Machines (RBMs), Deep Belief Networks (DBNs), and Generative Adversarial Networks (GANs) are a few examples (GANs)[6].

1.2 Used of Deep learning in medical image analysis

- CLASSIFICATION:Computer-Aided Diagnosis is another name for classification (CADx). In 1995, Lo et al. developed a CNN for detecting lung nodules on chest X-rays [45]. To determine if an area had a lung nodule, they utilized 55 chest x-rays and a CNN with two hidden layers[7]. Deep learning development in this modality is believed to have been boosted by the relative availability of chest x-ray pictures. 150,000 training samples from 1850 chest x-ray scans. They categorized the orientation of the pictures into frontal or lateral views with near-perfect accuracy using a modified pre-trained Google Net CNN. Although this job of determining the orientation of the chest x-ray is of little clinical use, it does show the efficacy of pre-training and data augmentation in learning the necessary picture metadata as part of a completely automated diagnostic work-flow. Pneumonia, often known as a chest infection, is a frequent health issue that is easily treated all around the globe.used 112,000 pictures from the ChestXray14 dataset to identify 14 distinct illnesses observed on chest x-rays using a modified Dense Net with 121 convolutional layers dubbed Chex Net. Chex Net classified the 14 illnesses with state-of-the-art accuracy; the pneumonia classification, in particular, received an Area Under Curve (AUC) score of 0.7632 using Receiver OperatingCharacteristics (ROC) analysis[3]. Chex Net also equaled or outperformed the performance of four individual radiologists, as well as a panel of three radiologists, on a test set of 420 pictures. Based on 1010 labelled CT lung images from the Lung Image Database

Consortium (LIDC-IDRI) dataset. Utilized CNNs in combination with Support Vector Machine (SVM) and Random Forest (RF) classifiers to identify lung nodules as benign or malignant[3]. They utilized three parallel CNNs, each with two convolution layers, to extract features from picture patches at various sizes. The learnt characteristics were utilized to create an output feature vector, which was subsequently categorized as benign or malignant using either an SVM with radial basis function (RBF) filter or an RF classifier[8].Their technique correctly identified nodules with an accuracy of 86%, and they discovered that it was resistant to various amounts of noise input. Three-dimensional CNNs were utilized to interpolate missing imaging data between MRI and PET images.The researchers looked at 830 individuals using MRI and PET scans from the Alzheimer Disease Neuroimaging Initiative (ADNI) database. 3-D CNNs were trained to recreate PET pictures from patients who did not have them, using MRI and PET scans as input and output, respectively[3]. Their reconstructed PET pictures almost matched ground truth illness classification findings, but one drawback is that overfitting problems were not addressed, limiting the technique's potential generalizability[5].

- LOCALIZATION: The practice clinician is less likely to be interested in normal anatomy localization, but it may have uses in anatomy teaching. Localization may also be useful in completely automated end-to-end applications, in which the radiological picture is processed and reported without the need for human involvement. Used transverse CT image slices to build a two-stage CNN, the first of which detected local patches and the second of which differentiated the local patches by various bodily organs, resulting in better results than a conventional CNN. Used a CNN with five convolution layers to classify around 4000 transverse axial CT images into one of five categories: neck, lung, liver, pelvis, and legs. After using data augmentation methods, he was able to obtain a 5.9% classification error rate and an AUC score of 0.998. Utilized stacked autoencoders to identify the locations of the liver, heart, kidney, and spleen in 78 contrast-enhanced MRI images of the abdomen area harboring liver or kidney metastatic tumors. Depending on the organ, hierarchal characteristics were learnt across the spatial and temporal domains, yielding detection accuracies of 62 percent to 79 percent[8].

- **DETECTION:** Detection, also known as Computer-Aided Detection (CADe), is an important field of research since failing to detect a lesion on a scan may have serious implications for both the patient and the physician. The challenge for the 2017 Kaggle Data Science Bowl was to identify malignant lung nodules on CT lung images. For the competition, about 2000 CT images were published, and the winner, received a logarithmic loss score of 0.399. Their method utilized a 3-D CNN based on the U-Net architecture to isolate small patches before detecting nodules[9]. The result was then input into a second stage, which consisted of two completely linked layers for cancer probability categorization. On CT images, assessed five well-known CNN designs for identifying thoracoabdominal lymph nodes and interstitial lung disease. Lymph nodes must be detected since they may be a sign of infection or malignancy. Using Google Net, they were able to obtain a mediastinallymph node identification AUC score of 0.95 and a sensitivity of 85% for mediastinal lymph node detection. They also demonstrated the advantages of transfer learning and the usage of deep learning architectures with up to 22 layers, as compared to the fewer layers used in medical picture analysis before.Overeat was a CNN that won the ILSVRC 2013 localization challenge after being pre-trained on natural pictures. Used Overfeat to predict the presence of nodules inside and around lung fissures using 2-dimensional slices of CT lung images orientated in the coronal, axial, and sagittal planes. They coupled this method with basic SVM and RF binary classifiers, as well as a Bag of Frequencies , an original 3-dimensional descriptor[1].

- **SEGMENTATION:** The study on CT and MRI mage segmentation includes a wide range of organs, including the liver, prostate, and knee cartilage, but there has been a lot of emphasis on brain segmentation, particularly tumor segmentation. The latter is particularly essential in surgical planning because it allows surgeons to pinpoint the precise borders of the tumor and therefore guide surgical excision. Neurological impairments such as limb weakness, numbness, and cognitive impairment would result if too much of the eloquent brain regions were sacrificed during surgery. Medical anatomical segmentation has traditionally been done by hand, with a clinician sketching contours slice by slice across a full MRI or CT volume stack. It is thus desirable to develop a system that automates this time-consuming process. Who examined different CNN architectures and metrics used in segmentation, wrote an outstanding overview on brain MRI segmentation.He also discussed a number of contests and datasets, including Brain Tumor Segmentation (BRATS), Mild Traumatic Brain Injury Outcome Prediction (MTOP), and Ischemic Stroke Lesion Segmentation (ISLES)[10].

- **REGISTRATION:** Although there are many potential uses for medical image registration,, their actual clinical usage is limited. In neurosurgery or spinal surgery, image registration is used to locate a tumor or a bony landmark on the spine in order to assist surgical tumor removal or spinal screw implant implantation. To align the pictures, which may be 2 or 3-dimensional, a reference image is aligned to a second image, termed a sense image, using different similarity metrics and reference points. The reference picture might be a pre-operative MRI brain scan, whereas the sense image could be an intraoperative MRI brain scan performed after a first-pass resection to see whether there is any remaining tumor and if further resection is needed. Layered convolution layers in an encoder-decoder manner using MRI brain images from the OASIS dataset to anticipate how an input pixel would morph into its final form. They used a large deformation diffeomorphic metric mapping (LDDMM) registration model, which resulted in significant reductions in computing time.

2. DISCUSSION

Deep learning is the most advanced machine learning technique. Deep learning's success in a variety of pattern recognition applications has sparked enthusiasm and raised hopes that deep learning, also known as artificial intelligence (AI), would revolutionize health care. In certain applications, early investigations of deep learning applied to lesion identification or classification found that it performed better than traditional methods or even better than radiologists. The possibility of using deep-learning-based medical image analysis to improve the accuracy and efficiency of different diagnostic and treatment procedures has sparked fresh research and development initiatives in CAD. Despite the excitement around this new age of machine learning, there are many obstacles to developing and using CAD or AI technologies in clinical practice. We will address some of these problems in this chapter, as well as the efforts required to build strong deep-learning-based CAD tools and incorporate them into clinical workflows, thus progressing toward the objective of offering dependable intelligent assistance for patient care.

3. CONCLUSION

New areas of research include content-based image retrieval, picture report or caption creation, and physical object manipulation using LSTMs and reinforcement learning including surgical robots is all new fields of study.Below are a few cutting-edge applications that cut beyond conventional medical image analysis categories. Presented an intriguing application in which GANs were utilized to create CT brain pictures from MRI scans. This is significant because it implies patients may be able to avoid receiving ionizing radiation from a CT scanner entirely, reducing costs and increasing patient safety. Nie also took use of GANs' capacity to create better, higher-resolution pictures from native photos, reducing the blurriness in CT scans. Applying

resolution enhancement methods to produce higher-quality MRI pictures might be a beneficial advance. High-tesla (and therefore more expensive) MRI scanners are required for high-quality MRI pictures. As a result, using an algorithm to produce high-quality MRI pictures on a lower-field-strength scanner will save healthcare expenses. Chang presented a new application in the fledgling field of radio-genomics, in which radiological pictures are used to infer the tissue's underlying genetic origin. He initially learned latent characteristics from MRI scans of glioblastomamultiforme (GBM), a malignant brain tumor, using the The Cancer Genome Atlas GlioblastomaMultiforme (TCGA-GBM) data collection using an autoencoder.The learnt characteristics were then used to categorize an MRI scan into one of four known molecular sub-types of GBM using a fully connected classifier layer. Chang's study, although still preliminary, has the potential to identify a GBM sub-type and eliminate the requirement for surgical sample and genetic tests. The technique's applicability to malignancies in other parts of the body is also intriguing.

Utilized histological pictures to identify lung cancer subtypes and forecast frequent genetic alterations in a similar way. Knowing your genetic alterations may help you predict how long you'll live and which treatment to use. Their approach beats a human pathologist, with AUC values ranging from 0.73 to 0.86 for genetic mutation prediction.Presented a groundbreaking study that combined content-based image retrieval (CBIR) with computer-assisted diagnosis (CADx). In other words, their model segmented a lesion on a query picture and compared it to segmented lesions in their database, which included 400 Regions of Interest generated from the Digital Database for Screening Mammography (DDSM). The Euclidean distances between the representation vectors of the query lesion and database lesions served as the foundation for comparison. The program then generates reference pictures as well as a probability of a lesion being benign or malignant.The shortage of data in medical image analysis is two-fold and more acute: there is a general paucity of publically accessible data, and high-quality labelled data is even scarcer. The majority of the datasets in this study include less than 100 patients. Despite the limited training datasets, the articles in this study indicate rather acceptable performance in the different tasks, suggesting that the situation may not be as bad as it seems. Provided a partial solution to the issue of how many pictures are required for medical image analysis training. He tested the precision of a CNN with Google Net architecture in categorizing individual axial CT scans into one of six bodily regions: the brain, neck, shoulder, chest, belly, and pelvis. On a test set of 6000 pictures, accuracies of 88-98 percent were achieved using 200 training images. While classification into different bodily areas isn't a practical medical image analysis job, his work suggests that the issue might be solved. It's possible that the ability to classify a limited dataset is due to inherent picture homogeneity among patients, as opposed to the near-infinite diversity of nature images, such as dogs of varied breeds, colors, and postures.

ABSTRACT

Color, label data, and applications are only a few of the factors that will impact our choice of electrical wire. The information written on the wire shell is all you need to choose the appropriate wire for your house. Frequently, the same term (wire or cable) is used to identify the same object, despite the fact that they are fundamentally different. A wire is a single electrical conductor, whereas a cable is a collection of wires encased in sheathing. The word cable came to mean a nautical line of several ropes used to anchor ships, as well as an electrical context in which cables (similar to wires) are used to transfer electrical currents. Multiple insulated conductors in an overall jacket, with helical tape steel or aluminum armor, or else steel wire armor, as well as a worldwide PVC or lead jacket to protect against moisture and physical damage, may be used in cables for manufacturing, commercial, and apartment buildings. Weaved bronze wires may safeguard cables designed for extremely flexible usage or in maritime applications. Under the usual construction code, electricity or power supply cables (such as computer networking) that are run in or through air-handling areas (plenums) of office buildings must either be covered in metal conduit or assessed to minimal flame and smoke production.

1. INTRODUCTION

In a building, electrical wiring refers to the cabling and connected devices such as switches, distribution boards, plugs, and lighting. To help with installation, wiring is subject to safety regulations. Allowable wire and cable types and diameters are determined by the circuit operating voltage and electric current capacity, as well as environmental factors such as ambient temperature range, moisture levels, and sunshine and chemical exposure. Voltage, current, and functional specifications apply to associated circuit protection, control, and distribution devices in a building's wire system. Local, state, and regional wiring protection

codes differ. The International Electro-technical Commission (IEC) is struggling to harmonise wiring standards between member countries, while significant differences in design and installation necessities still exist. An electrical cable is a collection of one or more wires that are bundled together or run side by side to transmit electric current[1], [2].

A cable rally is made up of one or more electrical cables and the connectors that go with them. A cable rally is not always appropriate for connecting two devices, but it may be used as a supplement (e.g. to be soldered onto a printed circuit board with a connector mounted to the building). Cable assemblies may also use a cable tree or cable harness system ", which is used to link many terminals together.

1.1. Electrical Wire Types:

Electrical cables are divided into five categories i.e., triplex, main feeder, panel feed, non-metallic sheathed electrical wires, single strand electrical wires as shown in Figure 1:

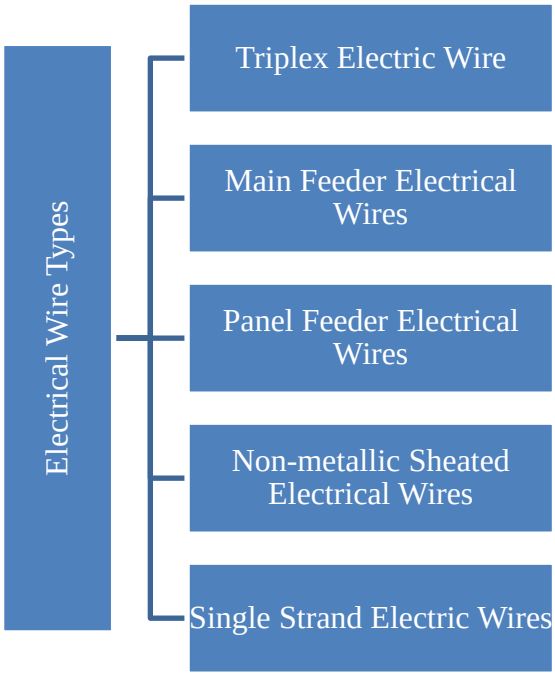

Figure 1: Illustrates the types of electrical wire used for wiring of electric circuit.

1.1.1. Triplex Electrical Wires:

Outside of weather heads, triplex electrical wires are frequently used in single-phase service drop cables. They are made up of two insulated aluminum wires that are wrapped around a third bare wire that serves as a public neutral. In addition to being grounded at both the electric meter and the transformer, the neutral is usually of a smaller gauge[3], [4].

1.1.2. Main Feeder Electrical Wires:

The wires that connect the service weather head to the home are known as central power feeder wires. They're constructed of stranded or solid THHN wire, with the cable placed 30 percent longer than the load required.

1.1.3. Electrical Wires for Panel Feeds:

Panel feed cables are typically black insulated THHN wire. These are used to power the circuit breaker panels and the core junction container. The cables must be rated to 50 percent higher than the actual load, much as core power feeder electrical lines.

1.1.4. Non-Metallic Sheathed Electrical Wires:

Romex, or non-metallic sheathed electrical wire, is used in most buildings and has two to three conductors, each with plastic insulation and a bare crushed wire. The separated wires are further shielded by a layer of non-metallic sheathing. This kind is popular in-house wiring since it is somewhat cheaper and comes in a variety of ratings (10 to 20 amps).

1.1.5. Single Strand Electrical Wires:

Single strand wire is used in a variety of applications, including THHN wire. Every wire is distinct, and several wires may undoubtedly be brought together via a conduit. Single-strand electrical wires are the most popular option for wire-in-pipe configurations.

2. CLASSIFICATION OF ELECTRICAL-CABLES

There are presently ten distinct types of cables available, with uses ranging from transmission to heavy industrial. The following are a few of the more often used ones:

2.1. Sheathed-Cable (Non-Metallic):

Non-metallic building wire, or NM wires, is another name for these cables. Apart from a bare wire to grounding, they have a flexible plastic jacket with two to four wires (TECK cables are roofed with thermoplastic insulation). Special variants of this cable are used for subterranean or outdoor applications, whereas non-metallic encased cables such as the NM-B and NM-C are the most prevalent kind of interior residential cabling[5].

2.2. Feeder-Cable (Underground):

These cables are similar to NM cables, except that instead of each electrical wire being separately wrapped in thermoplastic, the wires are gathered and incorporated in the flexible material. UF cables come in a variety of gauge diameters and are often used for outdoor lighting and in-pounded applications. Their great water resistance makes them suitable for wet locations such as gardens, as well as open-air lights, pumps, and other similar applications[6].

2.3. Metallic Sheathed Cable:

Metal-sheathed cables, also known as armored or BX cables, are often used to deliver mains power or heavy equipment. Three simple stranded copper wires (one for current, one for grounding, and one for neutral) are insulated with cross-linked polyethylene, PVC bedding, and black PVC wrapping. Outdoor applications and high-stress installations often utilize BX cables with steel wire sheathing.

2.4. Cable with Multiple Conductors:

Because it is easy to use and well-insulated, this is a cable type that is frequently used in houses. Multi-conductor or multi-core (MC) cables have several conductors, each of which is separately insulated. In addition, an exterior insulating layer has been added for additional security. In industries, several types are utilized, such as the audio multicore ‘snake cable' used in the music business.

2.5. Coaxial Cable (F):

A tubular insulating coating protects an inner conductor that is further bordered by a tubular conducting shield and a coaxial (sometimes helix) cable may also have an outer sheath for

additional insulation. These cables are often used to transport television signals with connecting video equipment and are referred to as "coaxial" because the two inner shields share the same geometric axis.

2.6. Twisted Pair Cable (Unshielded):

This kind is made up of two wires that have been twisted together, as the name implies. This cable is ideal for signal transmission and video applications since the individual wires are not shielded. UTP cables are often used in telephones, security cameras, and data networks because they are less expensive than coaxial or optical fiber connections. Because UTP cables with copper wires or solid copper cores are flexible and can be readily bent for in-wall installation, they are a popular option for interior usage[7].

2.7. Ribbon Cable (H):

Ribbon cables, which include different conducting wires that run parallel to one other on a flat surface and resemble flat ribbons, are often used in computers and peripherals. These cables are very adaptable and can only be used for low-voltage applications.

2.8. Underground Cable:

These cables, also known as DBCs, are specially-designed coaxial or bundled fiber-optic cables that do not need any additional sheathing, insulation, or piping before being buried below. A strong metal core with several layers of banded metal sheathing, thick rubber shells, shock-absorbing gel, and waterproof wrapped thread-fortified tape are among the features. They are a common option for transmission or communication needs because to their high resistance to temperature fluctuations, moisture, and other environmental factors[8]. Figure 2 shows the construction of electric cable.

1. Twin (Lead-Cable): Similar to TV blues radio, they are flat two-wire cables used for transmission between an antenna and receiver.

2. Twin-axial Cable: This is a kind of coaxial cable that has two inner conductors instead of one and is used to transmit high-speed communications across small distances.

3. Paired Cable (L): That cable is usually used in (DC or low-frequency AC)-uses and applications due to its two independently insulated conductors.

4. Twisted Pair (M.): The inner insulated wires of this cable are twisted or interwoven, similar to paired cables.

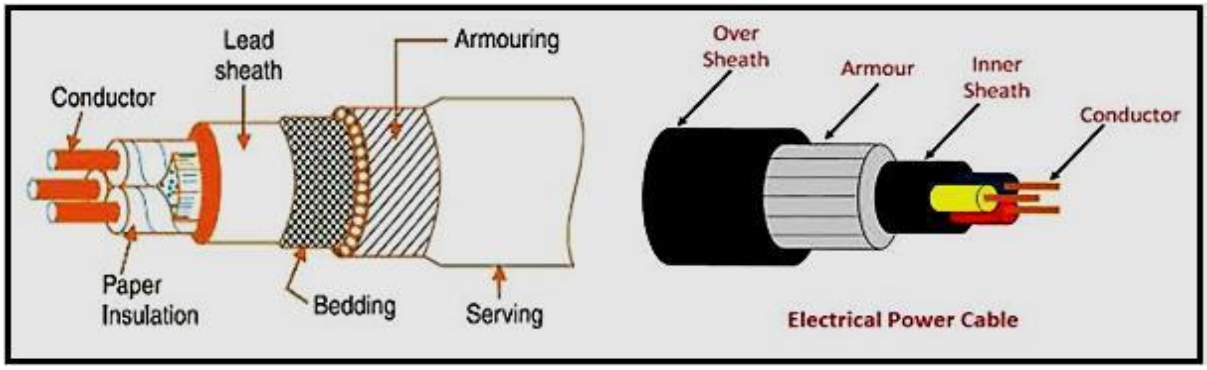

Figure 2: Illustrates the construction of underground electrical cables[9]**.**

More regular wiring fluctuations can be calculated in a light lucrative environment, big tools may be fixed, and specific temperature or moisture conditions can apply. Heavy industries

have more stringent wiring requirements, such as extremely high currents in addition to higher voltages, frequent equipment layout changes, corrosive, damp, or explosive environments. Special restrictions may apply to the installation of electrical equipment in hazardous locations in facilities that handle flammable gases or liquids.There are presently ten distinct types of cables available, with uses ranging from transmission to heavy industrial. The following are a few of the more often used ones:

3. MODERN WIRING MATERIALS:

Two to four wires coated with thermoplastic insulation, plus a bare wire for grounding (bonding), are bordered by a flexible plastic jacket in modern non-metallic sheathed cables, such as types NMB and NMC (US and Canadian). Before the plastic jacket is placed, some versions wrap the individual conductors in paper. Special variants of non-metallic encased cables, such as US Type UF, are intended for direct underground burial (sometimes with a separate mechanical barrier) or outdoor usage when UV exposure is a concern. These cables are distinguished by their moisture-resistant structure, the absence of paper or other absorbent fillers, and their UV resistance formulation. Because of its excellent moisture resistance, rubber-like synthetic polymer insulation is utilized in industrial and electrical cables placed underground. Insulated cables are rated based on their maximum working temperature and allowed operating voltage at the conductor surface. A cable may have several use ratings for different purposes, such as one for dry installations and another for moisture or oil exposure.

Because the wiring does not need to be particularly flexible, single conductor construction wire in tiny diameters is usually solid wire. The circuit voltage, heat rating, and environmental circumstances (moisture, sunshine, oil, and chemicals) under which they may be used are all used to grade building wire. A voltage (to neutral) rating and a maximum conductor surface temperature rating are both assigned to a wire or cable. The quantity of current a cable or wire may safely carry is determined by the circumstances of installation. Conductors bigger than 10 AWG (or approximately 6 mm2) are stranded for installation flexibility, but they aren't flexible enough to be used as an appliance cable. Cables for industrial, commercial, and residential structures are available "involve a large number of insulated conductors in an overall jacket, with helical tape steel or aluminum armor, or steel wire armor, and perhaps a PVC or lead jacket for moisture and physical damage protection. Weaved bronze wires may protect cables designed for extremely flexible usage or in maritime applications. Under the model building code, power or communications cables (such as computer networking) that are run in or through air-handling areas (plenums) of office buildings must be enclosed in metal conduit or certified for minimal flame and smoke generation. Electrical cables link two or more devices, allowing electrical signals or power to be sent from one to the other. Cables are used for a variety of reasons, and each one requires customization. In electronic equipment, cables are often used for power and signal circuits. Undersea cables are used for long-distance communication. Electricity cables, particularly high-voltage wire, are used for bulk transfer of alternating and direct current power. Electrical cables are widely utilized in the wiring of buildings for lighting, power, and control circuits that are permanently fixed. When compared to alternative wiring techniques, installation labor is reduced since all of the circuit conductors needed may be placed in a cable at the same time.

3.1. Sizes of Stranded Wire AWG:

AWG gauges are used in the same way "Wire with strands is referred to as stranded wire. It refers to a wire with a cross-sectional area equal to the sum of the cross-sectional areas of all the individual strands; gaps between strands are not included. These gaps comprise approximately 10% of the wire area when constructed with circular strands, necessitating a wire that is about 5% thicker than comparable solid wire. The overall AWG size, the number

of strands, and the AWG size of a strand are all used to specify stranded wires. A slash separates the strand number and the AWG of each strand. For example, a 22 AWG 7/30 stranded wire is a 22 AWG wire made" from seven strands of 30 AWG wire, figure 3.

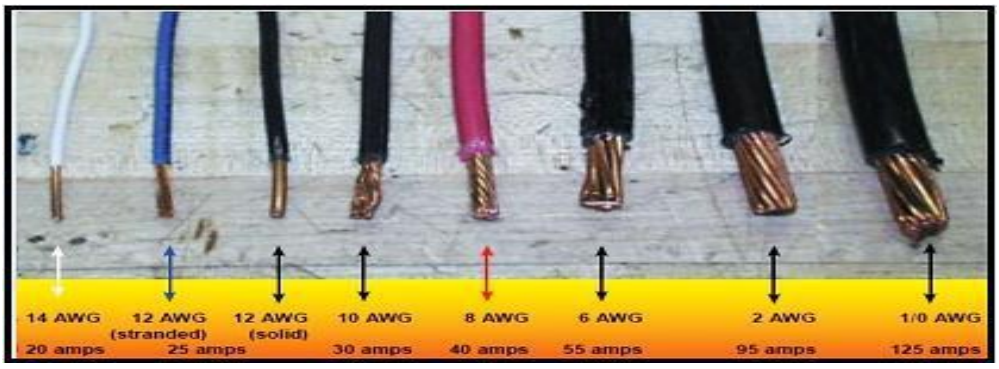

Figure 3: Represents stranded wires of different sizes used for wiring of circuit[10]**.**

4. DISCUSSION

An electrical cable is a physical assembly made up of one or more conductors, each having their own insulation and optional screens, as well as separate coverings, assembly protection, and protective covering. Wires may be stranded to make electrical cables more flexible. Smaller individual wires are twisted or braided together in this technique to create bigger, more flexible wires than solid wires of equal size. The greatest flexibility is gained by bundling tiny wires before concentric stranding. Copper wires in a cable may be bare or plated with a thin coating of another metal, most often tin, but also gold, silver, or other metals. Tin, gold, and silver are less prone to oxidation than copper, which may help extend the life of wires and make soldering simpler. Tinning is also utilized to keep the strands lubricated. Rubber insulation was removed with the aid of tinning. The cable is extendable (CBA – as in telephone handset cords) because of tight lays during stranding. Trunking, cable trays, cable ties, and cable lacing are all options for securely fastening and organizing cables. Strain relief devices or cable ties may be used to secure continuous-flex or flexible cables used in moving applications inside cable carriers. Current tends to flow along at high frequencies "the conductor's outer surface the skin effect is the term for this.

These effects are frequently undesirable, resulting in unwanted energy transmission that may negatively affect nearby equipment or other parts of the same piece of equipment, as well as unwanted noise pickup that may mask the desired signal being carried via the cable, or, if the cable is carrying power supply or control voltages, pollute them to the same extent. Because pick-up and transmission are basically related to cable length, the initial answer to these issues is to keep cable lengths in buildings low. The second option is to direct wires away from potential problems. There are also certain cable designs that reduce electromagnetic pickup and transmission. Shielding, coaxial geometry, and twisted-pair geometry are three of the most important design systems.

The electrical concept of the Faraday cage is used in shielding. The cable is completely wrapped in foil or wire mesh over its whole length. All cables going through this shielding layer will be isolated from external electrical fields to a considerable degree, especially if the shield is linked to a constant voltage source like earth or ground. Low-frequency magnetic fields, such as magnetic "hum" from a nearby power transformer, are not well protected by simple shielding of this kind. On cables with a voltage of 2.5 kV or higher, a beached shield collects leakage current and capacitive current, protecting people from electric shock and balancing load on the cable insulation.

The use of a coaxial design aids in "Along with pickup, further decrease low-frequency magnetic transmission. The foil or mesh shield has a circular cross section in this configuration, and the inner conductor is located precisely in the middle. This causes the voltages involved to be split into two almost equal magnitudes that cancel each other out through a magnetic field between the shield and the core conductor. Two wires of a cable are twisted around each other to form a twisted pair. Put one end of a pair of wires in a hand drill and spin while keeping modest strain on the line to illustrate this.When the wavelength of the interfering signal is longer than the pitch of the twisted pair, opposite lengths of wire produce opposing voltages, which tends to negate the impact "because of the interfering.

5. CONCLUSION

Wherever cables enter electrical equipment, they are usually protected with specific fittings; this may be a simple screw clamp to keep jacketed cables dry, or a polymer-gasketed cable connector that automatically engages the amour of an armored cable and provides a water-resistant connection. Where the cable runs through locations where flammable gases are present, special cable fittings may be used to prevent explosive gases from flowing through the inside of jacketed cables. Cables must be maintained at their entry to devices and at regular intervals throughout their runs to prevent loosening of the companions of individual conductors. To provide conductors for vertical cable lines in big structures, unique designs are required. Unless the fitting is rated or described for several cables, just one cable is usually allowed per fitting. They must also withstand salt water or salt spray corrosion, which is achieved by using thicker, specifically designed jackets and tinning the individual wire supports.

ABSTRACT

In order to reduce emission and noise in vehicle exhaust, an Aqua Silencer is used. It's made of activated carbon, a perforated tube, and an outer shell. In other words, an Aqua Silencer is a modified form of a standard silencer designed to reduce harmful emissions from an IC engine's exhaust into the atmosphere as well as to reduce noise generated by dampening techniques that include water, thus the name. Pollution continues to rise on a daily basis. Exhaust from cars and industry is the most significant cause of pollution. As a result, a replacement technology known as Aqua silencer has been developed to reduce harmful pollutants from engine exhaust. An Aqua silencer is a device designed to filter pollutants such as CO, UBHC, NOx, and Lead generated by vehicles. It works using a charcoal layer, a perforated tube, and water. Due to the presence of water, noise levels are also decreased when compared to an open area. As a result, it is given the name AQUA SILENCER.

KEYWORDS:*Aqua Silencer, Charcoal, Emission Control, Noise, Water, Pollutants.*

INTRODUCTION

Almost usually realize that perhaps the automobile sector contributes significantly to pollution, therefore we use Aqua Silencer to reduce both air and sound pollution. Carbon monoxide, laughing gas, sulfur dioxide, and unburned hydrocarbons are among the exhaust gases produced by engines (UBHC). These poisonous fumes are very hazardous to both the environment and human health. With the use of activated carbon and lime water, Aqua Silencer is used to decrease pollutants and noise while also reducing their negative effects.

An Aqua Silencer is a device that regulates the discharge and turbulence in automobile exhaust. It is constructed using activated charcoal, a perforated cylinder, and an exterior casing. The motor's fumes line has a water silencer installed. The nitrous and sulfur compounds produced by the engine are channeled via the activated charcoal. When sound is delivered submerged, it is less audible than when it is delivered in the air. This is due to the presence of small sprockets in water particles, which reduces its sufficiency and, as a result, reduces the sound intensity. Because of this characteristic, water is used in this silencer, giving it the name Water SILENCER. It was tested in a single chamber 4-stroke diesel engine, and the noise and smoke

levels were much higher than with a standard silencer. In ic motors, a water silencer is utilized to limit the noise and discharge. The reason for choosing a water silencer is because, in today's world, air pollution has real-world consequences for humans and the environment (Figure 1).

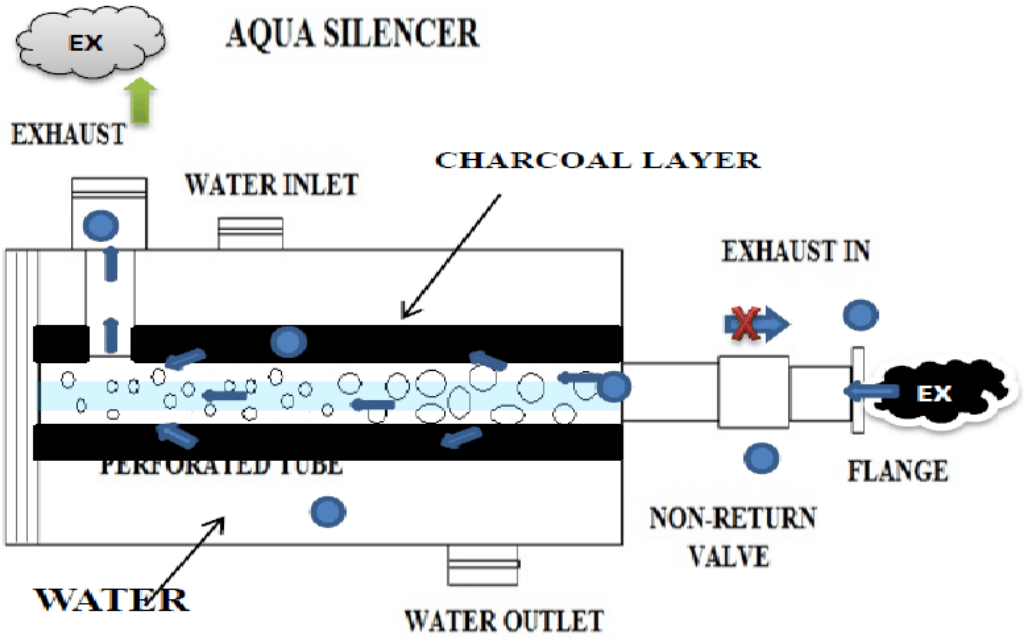

Figure 1: Illustrates the diagram shows an Aqua silencer

The primary source of air pollution is automobiles that release gases such as carbon dioxide, unburned hydrocarbons, and so on. In order to keep a strategic distance from these gases, we offer this water silencer, which is attached to the motor's fumes line. When sound is provided underwater, it is less audible than when it is given in the air. This is mostly due to little sprockets in water particles, which reduces its abundance and, as a result, reduces the sound intensity. The emanation may be limited by using the activated charcoal layer, which is very porous and forces more free valences, resulting in a high ingestion limit. As a result, consume the gases produced by the engine and contribute much less to the environment. The noise and smoke levels are much higher than with a conventional silencer, and there is no requirement for an exhaust system. It is also easy to install.

Modification of the Aqua Silencer

- Filler plug
- A coating of charcoal
- Tube with perforations
- Mesh built of wire
- Remove the drain plug
- Cylinder with a bypass
- The primary cylinder

Automobiles, which emit gases such as CO2, unburned hydrocarbons, and other pollutants, are the primary source of pollution. We shall employ an aqua silencer to reduce the emissions of those gases. It's attached to the engine's exhaust pipe. Underwater sound is less perceptible than sound generated in the atmosphere. This is due to the existence of tiny sprockets in water

molecules, which reduce the amplitude of the sound and hence the volume. Activated carbon layers and lime water are often used to reduce emissions. Because activated carbon is extremely porous and has additional free valences, it has a high absorption capacity and lime water chemically interacts with engine exhaust gases, releasing considerably fewer harmful gases into the environment. The conventional silencer reduces noise and smoke levels significantly; it does not need a converter and is simple to install.

Through a perforated tube, exhaust gas from the engine cylinder enters the twin filter silencer. Gas reaches the first filter of the silencer via the perforated tube. Perforated tube is a kind of tube with various diameter sections. As a result, high-mass bubbles are converted to low-mass bubbles via the perforated tube. Lime water interacts with harmful gases in the main filter, lowering their concentration. The gases are then sent through a secondary filter containing charcoal, which purifies the gases once more. Charcoal is very porous and has a lot of free valances. As a result, it has a high adsorption capacity. Because the sound generated in an aqua silencer beneath water has a lower amplitude than sound produced in the open environment, it lowers emission noise.

This occurs because tiny sprockets exist in water molecules, lowering the amplitude of emission gases and lowering the sound intensity. The most important component of the Aqua silencer is the perforated tube, which is made up of a number of holes of different diameters. On a perforated tube, there are usually four sets of holes. The activated charcoal layer that is pasted over perforated tubes may limit the emission utilizing extremely porous additional free is growing on our planet due to a significant rise in pollution. On our planet, pollution is a major problem. As a result, different significant efforts are needed to solve these issues. As a result, a replacement technology known as Aqua silencer has been developed to reduce harmful pollutants from engine exhaust. Because sound is common, these layers have a high absorption capacity. In an IC engine, it regulates noise and emissions[1]. It's attached to the pipe's exhaust; sound generated beneath water is less audible than sound produced in the air. The activated carbon layer and lime water are often used to reduce gas emissions. The conventional silencer reduces noise and smoke levels significantly; it does not need a converter and is simple to install. This silencer uses both charcoal and water, therefore it's known as a hybrid aqua silencer. It's useful in automobiles, industry, DG sets and DG machines, Marin and Boats, and it's also known as a hybrid universal aqua silencer. The Aqua Silencer is simple to install and does not need a converter. One of the most significant ways for effectively reducing harmful gases and noise is the use of an aqua silencer.

Ultimately, the combustion products escape into the atmosphere via the aperture. The dual filter silencer is more straightforward in terms of reducing emissions from engine exhaust gases utilizing a water and lime stone combination. The sound level is decreased by employing a water and lime stone combination since the back pressure remains constant. Sound is frequently reduced by utilizing water as a medium, and we may regulate exhaust emissions to a larger extent by employing limestone in water[2]. Because the amount of acidity level in twin filter silencer is anticipated to be below the harmful acidity, the water pollution is determined to be minimal. It emits no smoke or pollutants and has a low carbon footprint. As a result, the dual filter silencer lowers noise as well as pollutants. The performance of the dual filter silencer is almost identical to that of the conventional silencer. With its thin construction and light weight, the water silencer framework is intended to replace commonly used single unit silencers in motors. It has a major role in the commotion and gas outflow from engines. Air pollution has a dangerous effect on the human body, animals, and the environment. The main reason for using a water silencer is that air pollution is quickly increasing these days. The hazardous fumes vapor from the car are reduced by this framework[3].

The started charcoal layer surrounding the perforated cylinder and lime water restricted these outflows. The capacity of the charcoal layer to absorb emanation gases from the engine is great. These types of charcoal layers with lime water react artificially to outflow gases and alter the emanation gas compound design. The exhaust gases exit through the aperture into the atmosphere, and the smoke or emanation gases and clamor level in a water silencer differs significantly from that of commonly used silencers. The dual filter silencer is more straightforward in terms of reducing emissions from engine exhaust gases utilizing a water and lime stone combination. The sound level is decreased by employing a water and lime stone combination since the back pressure remains constant[4].

The most important component of the Aqua silencer is the perforated tube, which is made up of a number of holes of different diameters. On a perforated tube, there are usually four sets of holes. The activated charcoal layer that is pasted over perforated tubes may limit the emission utilizing extremely porous additional free is growing on our planet due to a significant rise in pollution.

LITERATURE REVIEW

The study of aqua silencer modification and development is uncommon. However, just a few academics have researched on silencer noise and opacity reduction. RaimoKabral et al. described a newly designed silencer that uses a micro-perforated (MPP) tube supported by a locally responding cavity. The combined impedance of the micro-perforate and cavity is selected to meet the theoretical optimum, known as the Cremer impedance, in the frequency range of interest at the mid-frequency. It is simple to make a small silencer with substantial damping (say > 30 dB) at a range wider than an octave due to the high damping obtained at the Cremer optimum (hundreds of dB/m). Based on a light-duty vehicle application, both simulations and experimental testing of the new silencer are given[5].

P. Krause et al. are working on a semi-active muffler that adjusts the internal geometry of the muffler system or muffler in response to changes in engine conditions while driving. An active system that adds anti-noise or regulates the pulsing exhaust gas flow to smooth the gas pressure pulsation and achieve sound reduction in this manner. Different measurement findings reveal the capabilities and limitations of each system[6].

S. Martin et al. created a sound attenuation muffler. A passive muffler is classified as either a reactive or a dissipative muffler, depending on which of two noise-reduction methods it employs. A reactive muffler uses area discontinuities, branches (like a resonator), and flow reversals to reflect sound back to the engine compartment. For low to intermediate frequency ranges, this design offers excellent sound attenuation[7].

Srinivas has studied the extreme plastic deformation phenomena in silencer at el. In recent years, many severe plastic deformation (SPD) methods for creating ultra-fine grained materials in bulk metals and alloys have developed. The majority of the SPD techniques proposed are designed to process bulk materials; only a few methods, such as Equal-channel angular pressing (ECAP), High pressure torsion (HPT) technique, constrained groove pressing (CGP), and repetitive corrugation and straightening (RCS), can process sheet materials. During the ECAP process, an issue with less intersection filling and a moveable bottom wall arises. The solution to this issue is to maintain back pressure, which increases die filling and makes strain distribution more uniform[8].

Renato Barbieri et al. presented a technique for muffler shape design that combines finite element analysis with Zoutendijk's feasible directions method. Their goal was to determine the size of the acoustic muffler while maximizing the transmission loss (TL) in the frequency range of interest. For TL assessments, the enhanced four parameters technique is utilized, and the Helmholtz equation is numerically solved using the finite element method (FEM)[9].

The nonlinear free vibration response of shear deformable laminated composite and sandwich plates was studied by Manoj Kumar et al. For the study of the issues, the authors utilized a meshless method based on the multi quadric radial basis function (MQRBF). Particle mixing, bubble formation, slug development, and other factors influence heat and mass transport processes directly in fluidized bed hydrodynamics, according to Apurv Kumar. The quantity of air supply is substantially decreased under vacuum circumstances, resulting in fluidization properties that are comparable to those seen under atmospheric conditions, according to the author[10].

DISCUSSION

Gases emitted by vehicles, such as carbon dioxide and unburned hydrocarbons, are the primary source of air pollution. In order to address this significant contributor, the study focuses on modifying traditional silencers by proposing a modified Aqua silencer that reduces pollutant production. The Aqua silencer is installed similarly to a normal silencer, with minimal changes to the engine's exhaust pipe. The activated charcoal layers in the modified aqua silencer regulate emission. The silencer effectively absorbs hazardous gases from the atmosphere, making the vehicle environmentally friendly. Aqua silencer also tackles the issue of noise pollution, since sound generated in water is less perceptible because to tiny sprockets in water molecules that reduce the amplitude and hence the sound intensity. However, before the automotive industry uses aqua silencer, a few obstacles and difficulties mentioned in this paper must be properly solved.

CONCLUSION

The aqua silencer uses a perforated tubing, lime water, and charcoal to reduce the emission gases out from engine exhaust. The sound level is decreased by utilizing perforated tube since the back pressure remains constant. By utilizing a perforated tube, the fuel consumption stays the same as in a traditional system. By using water as a medium, the sound may be reduced, and we can regulate the exhaust emission to a larger extent by using activated carbon in water. Because water is used as a medium, sound is reduced, resulting in pollution-free emissions and smoke-free systems. These systems are very low-cost. Both four-wheelers and two-wheelers are equipped with this equipment. It is crucial in many sectors. It efficiently removes impurities within exhaust gases and lowers noise by utilizing activated carbon and perforated tube, while maintaining constant back pressure and using the same amount of fuel as a traditional silencer. It is a non-polluting, smokeless emission. Experiments have shown that the aqua silencer is efficient in decreasing gas emissions from engine exhaust. The use of water as a medium reduces sound levels, and the use of activated carbon in water provides virtually pollution-free and smokeless emissions, as well as being cost-effective in the long run. The performance of the aqua silencer is almost identical to that of the conventional silencer. It's often found in industrial engines and, with a little creativity, in heavy-duty automobiles. The smoke content of the exhaust gas was tested before and after treatment, and it was discovered that there was a significant decrease in emissions, as shown by the test findings.

3D PRINTING FOR CUSTOMIZED FOOD FABRICATION

Sarita Jangra*

Department of Pharmacy,
TeerthankerMahaveer University, Moradabad,
Uttar Pradesh, INDIA

ABSTRACT

The very first generations foods printing concept ideas and working models are presented in this research, with the goal of revolutionizing personalized food production via 3D printing (3DP). Unlike mechatronics food manufacturing techniques that aim to automated manual procedures for mass production, 3D food printing combines 3D printing with electronic cooking to create food items that can be customized in form, color, taste, texture, or even nutrition. This expands customisation possibilities to the industrial cooking industry while also introducing creative skills to fine dining. On the basis of fabrication platforms and printing materials, the chosen samples are evaluated. For single or multiple application, a comprehensive description of various 3DP technologies and their associated dispensing/printing method for 3D personalized food manufacturing is presented. Food printing's effects on customized health, on-demand food manufacturing, food manufacturing technology, and process design are ultimately discussed. Their use in home cooking and catering may offer not only an engineering approach for customized meal design and nutritional management, but also a possible tool to reconstitute a customised food system.

KEYWORDS: *Customized Food Fabrication, Food Manufacturing, 3D Printing, And PlatformDesign.*

INTRODUCTION

Customized food items are in high demand, as well as the majority of them are presently developed and produced by highly educated craftsmen. The price is quite expensive for such a little number of components. One of the possible solutions to overcome this gap is three-dimensional (3D) food printing, also known as Food Layered Manufacture. Its goal is to stack create 3D custom-designed food items without the need for entity equipment, moulding, or human involvement. As a result, this technique may improve the production efficiencies and reduced production costs for the creation of personalized food items. Eating is one of our most essential activities, and a robot chef able to follow instructions will have a wide range of uses in both domestic and industrial settings. Making cookies robots, for instance, can find ingredients, combine them in the proper sequence, and put the resultant batter in an ovens baking pan. These robots, which are outfitted with library, can execute fundamental manipulating activities such as

picking up, putting down, and pouring these microelectronics methods are often employed in conventional food industry for huge quantity to replace manual operations. They can significantly decrease workload, labor costs, and food productivity improvement. Food producers are ecstatic about such advancements, but they are unclear about the reasons for and motivations for creating food printing methods and their distinct characteristics. As a result, a comparison of the two methods is required.[1]

Food printing differs from other robotics-based technology in that it combines 3D printing (3DP) with digital gastronomy methods to create food items that can be mass customized in form, color, taste, texture, and even nutritional value. 3DP is a digitally controlled, robotic building technique that creates complicated solid structures layer by layer and fuses them together via phase transformations or chemical processes. The goal of digital gastronomy is to incorporate culinary processing information into food production so that our dining experiences extend beyond flavor to include all elements of gastronomy. Combining 3DP with digital gastronomy methods allows for digital visualization of food modification, opening up new possibilities for innovative food production at a low cost. As a consequence, a customized food design in the form of a digital 3D model will be immediately converted into a layered final product.[2]

1.1Food printer concepts and platform designs

The first phase of food printing concept ideas and models are becoming available to the general public. A few research programs, ranging from design concepts to in-depth study on material extrusion and deposition, have been completed in a short time.

A fast prototype and manufacturing technique for 3D food items, including a made - to - order birthday cake, was patented by Nanotek Instruments Inc. in 2001. However, there was no actual prototype created. Modern gastronomy was incorporated into the design of a meal generator in a lab contest. The goal of this idea was to use a tiny mechanical arm to print multiple materials and make a completely customized dinner out of ordinary food. Meal cartridges were developed by Philips Food Creation Printer to produce custom-designed food products layer-by-layer. To choose ingredients, amounts, forms, textures, and other culinary characteristics, an interactive user interface was suggested. This concept may be used for any kind of bespoke 3D food printing. However, all of these idea designs seem to be much too impractical to be implemented.Ingredients in electronic gastronomy may be decided based on internet nutritional content, personal and societal preferences. The three hypothetical ideas from the Massachusetts Institute of Technology (MIT) that incorporate a digital gastronomy concept into food printer design. Each one concentrated on a distinct element of cuisine, such as blending, modeling, and metamorphosis. These ideas appear to be more realistic than earlier concept designs, although they are still far from being technically viable.[3]

1.2 Food Printing Platform

The fundamental components of a food printing platforms are a three-axis XYZ stage (Cartesian coordinate system), distributing devices, and an interface. Such platform can handle food in real-time due to a machine three-axis motorised stage and materials feeding system. As according computer layout modelling and route planning, food content may be placed basically bullet points and layer by layer. At least four functionalities are suggested to create and customize new meals rather than merely automating the conventional food manufacturing process: measuring, mixing, dispensing, and cooking (heating or chilling) . In the present commercial or self-developed food printing systems, only the pouring and cooking features are provided.[4]

1.3 Commercial Platform-Based Food Printers

Researcher applied commercially available open source 3D printing platforms for foodstuff printing to simplify the design process and save development cycles. The most frequent change

is to replace an existing printer with a specifically designed dispensing unit and an extra valve to regulate material flow rate, or use a meal binder like starch mixes instead of conventional inkjet binder.[5]

However not particularly intended for culinary purposes, the Fab@Home system was one of the first desktop fabricators compatible with food ingredients. Frostruder MK2 was also utilized on the MakerBot platform to extrude frost, with two solenoids controlling the flow rate of creamy peanut butter, jelly, and Nutella . A food print platform with such a print head developed at the National University of Singapore. The platform is based on a Prusa i3 architecture that has been modified to include a self-developed extrusion printhead.[6]

1.4 Self-Developed Platform For Food Printers

Self-developed systems are constructed to meet specific needs, such as creating three - dimensional sugar structures with such a computer-controlled laser source , create a 3d cheese and chocolate artifacts from edible ingredients, or lowering the cost of free - form sweetener merchandise manufacturing with accessible hardware . They offer additional material dispensing options, allowing a suitable printhead to be developed and executed from a pool of candidates, as well as greater flexibility and optimization in dispensing settings and manufacturing processes.

Mechanical motions of the substrates and dispense head(s) are accomplished using a computer driven stage in both commercial and self-developed platforms. A 3d digital model may be transformed into multiple layer data (STL files) during the printing, and all these data can subsequently be translated into driven signals for stage drive motor through the controlled controller. The identical movement and pouring processes are repeated for each layer, each with its own unique form and size. These layers are combined and consolidated to create a full 3D model.[7]

Personal dietary has emphasized the idea of personalised food in terms of a person's health condition and body-type need, in addition to current nutritional preferences. Food printing may help people maintain a more precise diet by ensuring fresh, nutritious meals that are tailored to their specific requirements and tastes. It would have a substantial positive impact on the population's well-being. Food components, even those with well-known material characteristics, must be customized to unique formulas for each production in this instance. To get such highly personalized food items into every household, more work is needed.

1.5 Available Printing Materials

Pre-processing elements for 3D printing and increasing their thermal stability during post-processing have received a lot of attention. TNO proposes printing pureed meals to assist older individuals with chewing and swallowing issues. TNO also proposes customizing meals for elderly, athletes, and expecting women by changing dietary element amounts such as protein and fat. In general, the printability of current printing may be divided into two groups.[8]

- **Materials That Are Natively Printed**

Hydrogel, cake icing, cheese, hummus, and chocolate are all natively printed substances that can be extruded smoothly from a needle . In a finely ground 3d printing, a combination of sugars, starch, and mashed potato was tried as a powder material. For display purposes, a number of sugar teeth were created. Neither of these, however, are the primary dish of a meal. examined several traditional meals for printing, and most effective material was pasta dough, which was assessed by viscosity, texture, and solidifying characteristics. Taste, nutritional value, and texture of food items produced using natively printed materials may all be precisely regulated. Some natively printable materials are stable enough to retain their form after deposit and do not need additional processing steps, making them ideal for healthcare and space applications. Some

composite formulations, such as batters and protein pastes, may require a heating step after deposition. This will make it more difficult for food product structures to maintain their forms.[9]

- **Non Printable Traditional Food Material**

Rice, meat, fruit, and vegetables, which are widely eaten on a daily basis, are not printable by nature. Adding hydrogels to these solid materials has been authorized and used in various culinary areas to allow their extrusion capacity. Lipton et al. modified conventional food recipes using simple additions, resulting in complicated geometries and new formulas. While culinary techniques have previously been used to make solid meals and quasi liquids printed, it is difficult to test and alter the whole list. One possibility was to utilize a limited number of components to build a platform with a wide range of texture and taste options. A broad variety of textures (i.e. mouthfeels) may be produced by fine-tuning hydrocolloid concentrations. Cohen et al. investigated the structural requirements for post-processing materials such as protein pastes and cake mixes utilizing two hydrogels systems.

- **Food Processing**

To fully eliminate liquid ingredients from nutrient content, the food printing method does not need a significant source of energy. Fabricated layers do not need to be fully solid, but they must be stiff and strong enough to sustain their full load as well as the weight of succeeding layers before deforming or changing shape significantly.

After shaping, the bulk of traditional foods need post-deposition cooking, such as baking, steaming, or frying. Different degrees of heat absorption are involved in these activities, which result in texture that is not homogeneous The complicated interior geometries printed using a cookie recipe including cocoa modified substance were able to keep their form after baking.[10]

DISCUSSION

Food printer offer widespread skills to the commercial culinary sector while also introducing creative possibilities to gourmet dining. This allows for a high-value, poor food personalization process that is presently difficult to accomplish. It also includes research methods for manipulating the architecture of solid food items at various sizes. Because this technology is still in its initial phases of development, it is critical to comprehend its fundamental value and prospective commercial applications. Simultaneously, it is essential to keep track on technological advancements and related applications in order to determine how this new technology will satisfy customers' requirements and, possibly, alter people's lifestyles.

The majority of food manufacturing methods are designed for mass production, sacrificing culinary inventiveness and user control over forms, structures, and flavors. The food printer allows consumers to experiment with different food shapes and flavors. Previously, this customisation procedure necessitated the use of hand-crafted talents with a low production rate and an increased price. Meal print technologies have the potential to break down these boundaries by allowing home users greater flexibility in food customization design in terms of forms, colors, and flavors. It has the potential to create additional innovative solutions, such as customized chocolate shape, and full-color, customized graphics on solid food forms. Food printers will make it easier to adopt a cost-effective development approach. It is more cost effective to situate manufacturing facilities close to the end users. This may aid in the reconfiguration of the personalized food supply chain, allowing goods to reach customers in less time, at a lower cost, and with less resources.

Most food processing methods that include chemical and physical changes may not be compatible with 3D printing needs. This relates to architecture, texture, and taste, as well as

composition (ingredients and their interactions). Component compositions with a variety of combinations and manipulation circumstances may result in a wide range of textures in goods, some of which are unmanageable. In addition, the rigidity and strength of the print materials should be sufficient to withstand the weight of successive deposited layers as well as the heat impacts of the post-cooking process. In a nutshell, traditional food processing methods are unlikely to work in such a complex situation, and the entire process has to be redesigned. Pre-processing certain processes (e.g. gluten production and leavening) and substituting the other processes is an example (e.g. shaping and baking).

CONCLUSION

3D food printing has shown its worth by creating customized chocolate and basic homogeneous treats. These apps, on the other hand, remain basic, with restricted internal mechanisms and repetitive graphics. A systems approach to investigating print materials, platform design, printing methods, and their effects on food production is required. Furthermore, overall meal schematic design must be organized to encourage user creativity, the fabrication process must be defined to ensure optimal manufacturing outcomes, and a simulation to connect fabrication with nutritional management should be created. Meals printers may become part of an ecological system, where connected devices may purchase new ingredients, make beloved food on request, or even cooperate with physicians to design better diets, if an active open internet user interface is developed.

This article examines the evolution of food printing technology from idea to commercial machines. The two printer systems are utilized, as well as the printing experiment uses both natively readable and not printable conventional food components. Although there are a variety of food printing technology available, there is still a long way to go before they can be used commercially. Food printing has the potential to have a major impact on many kinds of food preparation, since it allows designers/users to modify shapes and materials with improved and unprecedented capacity, as seen in this technology review. This flexibility, whether used to home cooked food or caterer, may increase efficiency in delivering high-quality, freshly cooked food to customers, provide customized nutrition, and allow users to experiment with different tastes, textures, and forms to create whole different eating experience.

UZBEKISTAN

ABSTRACT

This article is devoted to the study of description of the wool's quality which is taken from the offspring of Karakalpak Sur Karakul rams in the experiments conducted in the limited liability company "Istiqlol Karakul Breeding" of Nurata district of Navoi region. Breeding and mating works are carried out on farms taking into account the high export potential and important features useful for the farm. Because although the barra in the herd has the same general characteristics in terms of skin characteristics and development, it may differ in its constitution or nasld characteristics.

KEYWORDS:*Bunch, Plum, Steel Sur, Red Belt, Barra Types, Silky, Glossy, Wool-Fiber Quality.*

INTRODUCTION

RELEVANCE OF THE SUBJECT: Today, the breeding of endangered animals is one of the most important zootechnical activities in improving the efficiency of the industry, improving the quality of products. It is noted that the quality of breeding sheep, the exportability of the flower type arise in different ways with different mating methods in the generations received from them. From this point of view, offspring are obtained by using various mating methods when obtaining breeding sheep on cattle farms. Homogeneous Barr-type mating serves to produce a certain type of lambs. And this makes it possible to predict in advance the color of lambs, the type of flower, the pattern, the quality of wool fiber that can be obtained on the farm.

Breeding and mating works are carried out on farms taking into account the high export potential and important features useful for the farm. Because although the barra in the herd has the same general characteristics in terms of skin characteristics and development, it may differ in its constitution or nasld characteristics. The high manifestation of the quality of sheep wool fiber causes a high appreciation of the skins. From this point of view, it is urgently necessary to study the quality of wool fiber, that is, its luster and silkiness, in the offspring of the sheep breed.

RESEARCH METHODS

The research work was carried out in the limited liability company "Istiglal Karakol" of the Nurotinsky district of Navoi region.

Based on the experience of scientists and pastoralists of the Karakul region of Uzbekistan, it is possible to distinguish Karakul sheep of Sur color, belonging to the type of Karakalpak breed, by the following colors [3; 56-57 AD]. In the Karakalpak hornbeam, the main inflorescences of spruce, apricot, steel and moon colors are present.

The underside of the wax wool fiber is intensely black, characterized by a sharp transition to white, as well as the presence of white wool fibers in the nasal part of the head.

Apricot is a multicolored skin with an excellent structure, the skin is divided into three zones according to the location of the amount of pigment in the wool fiber. The lower part of the wool fiber is characterized by a slow transition of black or dark color to light brown, and the upper part of the wool fiber is characterized by a milky white color. The wool cover is light yellow, the nasal part is covered with wool fibers of a milky white color.

The bottom of the steel fiber made of wool is black, characterized by a slow passage of steel or whitish color. The nose part consists mainly of steel-colored or light-white wool fibers.

The data obtained from the experiment were processed in the methods of variation statistics [1; 43 B., 2; 256B.]. The average Arithmetic index (X) of each sign, its error (Sx), was determined.

RESULTS OF THE STUDY

The silkiness of the wool coat depends on the amount of bristles and spikes contained in the wool, the length of the wool fibers, their thinness, tightness, The Shape of the flowers, as well as their location on the surface of the skin. Proceeding from these points of view, in the evaluation of the offspring of the breed of RAM, the silkiness indicators of the breed of wool coat were studied, and the data obtained were summarized in Table 1 below.

TABLE 1SILKINESS INDICATORS OF THE OBTAINED OFFSPRING WOOL COAT

Group of RAM	n	Silk spinning, % (X±Sx)		
		strong	normative	worthless
7,5-8,0 monthly generations of RAM				
Control	82	32,92±5,2	52,40±5,5	14,63±3,9
Experiment	95	35,78±4,9	52,63±5,1	11,57±3,3
In the offspring of Rams 17,5-18,0 months				
Control	87	35,63±5,1	50,57±5,3	13,79±3,7
Experiment	96	36,50±4,9	53,12±5,1	10,42±3,1

Analysis of Table 1 data shows that in the offspring of Rams aged 7,5-8,0 months, ipaximonity was 32,92% of lambs expressed in strong cinnamon, and the expression at the normative level was 52,40%. In the experimental group animals, there were cases of an increase in the indicators of expression of ipaximonality in strong and normative tailoring.

In the experimental group, it was determined that the expression of wool fibers in generations of Rams between the ages of 17,5-18,0 months in a strong and normative form was higher than in the control group. This led to an increase in the salinity of generations of quality received from Ram at the age of 17,5-18,0 months.

The ability of the wool coating to return light rays is called gilding. The luster of the wool coat is an important indicator, like silkiness. Well-expressed skins of this indicator are included in the upper classes.

The glossiness of the wool coating of the Spruce lambs will depend on the structure, shape and bending angle of the wool fibers when forming the pre-body layer of wool fibers. On the skin of lambs differ mainly strong, normative and inadequate species of lichen.

The results of the study of this indicator are presented in Table 2 below.

TABLE 2GENERATION OF WOOL COLLECTION

Group of RAM	**n**	**Shining, % (X±S_X)**		
		strong	**normative**	**worthless**
7,5-8,0 monthly generations of RAM				
Control	82	30,48±5,1	54,87±5,5	14,63±3,9
Experiment	95	33,68±4,8	54,73±5,1	11,57±3,3
In the offspring of Rams 17,5-18,0 months				
Control	87	34,48±5,1	52,87±5,3	12,64±3,5
Experiment	96	35,42±4,9	54,17±5,1	10,41±3,1

As can be seen from the table data, the strong expression of gilding in the offspring of 7,5-8,0 monthly control group Rams was 30,48%, the expression at the norm 54,87% and the insufficient level was 14,63%. In the generations of Experimental Group animals, there were cases of a decrease in the level of expression at an insufficient level, with a strong manifestation of luster.

In the offspring obtained from the control group Rams (17,5-18,0 months), gilding was observed to be 34,48% of the salinity of strong offspring and 52,87% of the salinity of lambs expressed at the normative level and to be higher than the rate of offspring obtained from Rams at the age of 7,5-8,0 months. In turn, the expression of luster in the offspring of the experimental group Animals at a strong (35,42%) and normative (54,17%) level decreased in contrast to the expression of the control group at an increased insufficient level compared to the control group. So it turns out that the offspring of the experimental group have higher qualities than the offspring of other group Animals.

CONCLUSION

In place of the conclusion, we can say that proper care and full-value nutrition of breed Rams have a positive effect on the high expression of the quality of wool-fiber obtained from them.

THE USE OF THE ARTISTIC TRADITIONS OF UZBEK FOLK ART IN THE LESSONS OF FINE ART

Abdirasilov Sunatulla Fayzullaevich*

*Candidate of Pedagogical Sciences,
Acting Professor,
Department of Fine Arts, Faculty of Vocational Education,
Tashkent State Pedagogical University named after Nizami,
Tashkent, UZBEKISTAN

ABSTRACT

The article examines the formation of communicative, cultural and art criticism competence and, at the same time, spiritual and moral education of students based on the use of works in the lessons of the fine arts of Uzbekistan. In the conditions of independence of the Republic of Uzbekistan, education and the upbringing of a new generation capable of implementing the idea of national revival is one of the priority tasks of the state and society. The implementation of a targeted policy in the field of education as a priority direction of the socio-economic, spiritual and cultural development of society, logically led to the adoption of the National Model and Program for Personnel Training.

INTRODUCTION

In the conditions of independence of the Republic of Uzbekistan, education and the upbringing of a new generation capable of implementing the idea of national revival is one of the priority tasks of the state and society.

The implementation of a targeted policy in the field of education as a priority direction of the socio-economic, spiritual and cultural development of society, logically led to the adoption of the National Model and Program for Personnel Training.

This conceptual model, which has no analogues in world practice, is designed taking into account the historical experience, domestic educational practice, as well as the experience and achievements of developed democratic countries in the field of education. This fundamental idea of the First President of the Republic of Uzbekistan I.A. Karimov found practical embodiment in the National Program for the Training of Personnel of the Republic of Uzbekistan.

An integral part of the National Program for Personnel Training is the national model, the implementation of which will solve the problem of forming a harmoniously developed, highly spiritual, free-thinking personality, responsible for the present and future of Uzbekistan.

Among the main components of the national model of personnel training, personality and lifelong education are the first to be named. The main task of lifelong education at the present stage is not only to provide deep knowledge, to form strong skills and abilities but also to develop the personality of the student in its uniqueness.

MATERIALSANDMETHODS

In solving problems as a system of embodying the values of culture and the formation of the student's personality, owning the cultural meanings of his own culture, an active search for the most effective technologies in the classroom and extracurricular activities in schools, universities, especially artistic-aesthetic, creative, pedagogical, continues, to familiarize the younger generations with the spiritual values of the people, its history, embodied in works of art and culture, including paintings by Uzbek artists. “So, what is special in the artistic culture of peoples is determined by far not only by customs and rules but by something more permanent. This is the nature of the region and a way to live, work and enjoy. These traits, developed by people's trials in historical events, are the ability to experience them. Finally, it is the very structure of feelings, the very perception of life, which develops in the course of the history of the people. It is all this that determines that special inner rhythm of art, which can be felt in folk art. It betrays the most intimate differences in national identity or national character since it determines not only their dependence on the place, climate and historical facts but, first of all, on the psychological makeup of the people.

This inner rhythm has been developed over the centuries. It determines the peculiarities of the people's world, in each case; it carries its own experience of space and time, its system of values. All this ultimately creates a unique spiritual reality of every nation” [1,2].

Folk arts and crafts have a long history and traditions dating back to antiquity. They are diverse. Such a unique set of types of folk art, which our Republic of Uzbekistan has, is relatively unavailable in others. “The tradition created by the artistic genius of the people plays a huge role in the national specifics of art” [2].

The historical development of folk crafts is a part of the culture of our society and it affects professional art, the formation of artistic tastes of children. Many researchers of folk decorative art note in their works the kinship of the worldview in the work of folk craftsmen and children, the basis of which they saw in a clear rhythm, ornamentation. It is believed that naivety and spontaneity are inherent in folk art, which is why it is so close and understandable to children, and therefore should play an important role in their aesthetic education. In the new program of fine arts, at modelling lessons, children get acquainted with the folk crafts of their region. These lessons provide profound opportunities for the development of figurative perception of works of folk art, which is now given great importance. The program requires teaching children to work, choosing a form, taking into account the transfer of the figurative state of the selected characters. And folk art, in particular, clay toys, helps us to convey the figurative state. The preservation of traditional arts and crafts from generation to generation is especially important. A peculiar and original artist Khamro Rakhimbaeva sculpts from white clay characters of folk epics based on folk national motives. Sheep with branchy horns are fabulous monsters with large ears and eyes. Each figurine has huge educational goals and is associated with an epic, fairy tale, folk epic. And although these toys are stylized, we can accurately tell which toy has which character. Children, however, feel all this very subtly and deeply. But they need a mood for imaginative perception, which the teacher can give, explaining new material, focusing on the figurative combination of works. For more complete assimilation of folk art by children, lessons on the perception of art are given before practical work. In the lessons of perception, dedicated to arts and crafts, students become widely acquainted with various artistic crafts of their people, reveal the distinctive features of individual crafts. Knowledge of folk traditions, the ability, for example: to

guess the homeland of toys by colour, ornament and shape, greatly facilitate practical exercises, making them more interesting and exciting. So, for example, it is necessary to comprehensively conduct classes on the perception of art and modelling in grade 4. First, there is a lesson in the perception of art, the purpose of which is to develop the ability to feel the beauty of the works of certain artistic crafts, to give an idea of the specifics and history of clay toys and works of folk crafts in their native land. In the next lesson of practical activity, students perform a relief tile/sculpture/. To complete the practical work, you should slightly change the topic of the previous lesson - the lesson of perception. In this lesson, we propose to familiarize students in more detail with the Uzbek national tile art that arose in the early period.

Particular attention should be paid to the plot content of the relief tile.

Stories about folk art should begin with the showing of video films ("Folk Craft of Uzbekistan"), colour reproductions, filmed in the homeland of a particular craft.Pictures of nature, architecture, painting, dishes, and clothes. The children must observe for themselves, identifying features of stylistic unity. It is important to accompany the slides with the necessary recordings of the masters themselves, fairy tales, epics, epics, legends and songs.

Especially song and music help to enter the art, to tune in to a subtle perception of beauty, connects the experience with the beauty of the native land, the talent of its masters.

In order to interest the children, the teacher himself needs to feel the beauty and power of the works of folk artists and help the child in this to enrich his own practice. Therefore, it is so important for the teacher to conduct conversations and exercises to identify the main artistic features of toys and then creative tasks that involve the use of the qualities they like. We believe that the student will be interested if the teacher does not give dry scientific data, but tries, as it were, to revive this or that subject. The teacher can even compose a fairy tale or a legend about a toy, for example, for one of the lessons we have compiled a legend about a cruel stone boy. “A long time ago, in the old days, a husband and wife lived. its shape resembled the figure of a little boy.

Something trembled in the woman's heart, she began to ask her husband to pick up the stone and bring it home. Then the husband agreed. And the wife began to look after the stone every day, to warm it so much that the stone could not stand it, came to life and turned into a little boy. But his heart remained stone. He was angry and cruel, offended the younger and rude to the elders. He brought a lot of evil to people. Then day and night the poor woman cried, she did not find herself joy in the stone son. And she decided that a man with a stone heart could not live among good people and asked Allah to turn him to stone again. Allah fulfilled the woman's request and turned the evil boy into a stone idol". This fairy tale was invented by the teacher to increase the students' interest in completing the practical task. Many children will be excited by this fairy tale and they will fashion a boy with an evil face.

Telling tales, legends, there were, teachers, give their speech a folk character. And this language becomes more understandable for schoolchildren, shows in them a creative stimulus, a desire to touch folk art with their own hands, create a toy, tile, painting. The tale can be used by the teacher in various ways.

Firstly, it is used to accentuate attention, to raise interest in practical activities; secondly, a fairy tale can also serve as a task. The teacher chooses a passage from a fairy tale, and the children complete the assignments based on this passage. Thirdly, the children can be invited to compose a fairy tale themselves and to do practical work according to their own fairy tale.

As we have already noted, it is impossible in fine arts lessons to do without slides, music, fairy tales, songs, literary works, without something that reflects and enriches people's life and everyday life. The teacher's speech bears some kind of national character if he uses certain

Uzbek sayings and fairy tales. All this facilitates the work of students, helps them to get closer to folk art. It is easier to acquaint children with Uzbek folk art because it is closer and more understandable to them; they often meet with it in everyday life. And if the children are offered to sculpt their deskmate, friend or relative, then they will gladly take on this task. Here you can also use old legends and students need to create their image, close to the image of a fairy tale, and send them in search of expressiveness.

At the end of the lesson, it is necessary to analyze student work, taking into account the figurative state of the characters chosen by the children.One of the valuable forms of work in this regard is the use of works of fine art, paintings by Uzbek artists, depicting their native nature, the typical way of life, familiar images of people, in general - the dear appearance of the homeland.

Display of a stand with reproductions on the topic; “Mother” of the famous paintings by Uzbek artists R.Ahmedov “Morning. Motherhood"and"Maternal Meditation", B. Dzhalalov"Mother", V. I. Burmakin"Baysun Madonna", N. V. Kashina"Samarkand Madonna", famous paintings by Italian Renaissance artists Leonardo da Vinci"Madonna Litta", Raphael Santi “Sistine Madonna”, Russian artist K.S. Petrov-Vodkin “Mother”.

The teacher concludes: A woman-mother gives each of us, be it a genius or a mere mortal, the most precious thing in the world - life.Women of all nationalities, speaking different languages: scorched by the sun and barely warmed by it in the Far North - they are all sisters in a single restless burst of feeling, the same when they bring a child to their breast.The whole world was fed by the breast of a woman, and the whole world fell asleep to her lullabies.Further, an analysis of the painting by the Uzbek artist Rakhim Akhmedov is given in detail. Examination of the reproduction of the painting “Morning.Motherhood ”is accompanied by the teacher's story: The world of his homeland, understood by the heart of the artist, is embodied in the works of R. Akhmedov. Boldly breaking the usual, traditional images of an Uzbek woman, R. Akhmedov paints the picture “Morning. Motherhood”.

For the first time in the art of Uzbekistan, the artist seems to secretly invade the hitherto carefully guarded side of life. The painter embodies the idea - mother and ever-changing nature is the beginning, the source of all life.Everything here is very earthly - the image of a mother sitting in a typical national pose, and a sleeping child, and nature with a wide panorama of fields, a ridge of blue mountains and young poplars trembling from the wind.At the same time, this real-world is surprisingly poetic, endowed with a sense of spring, the joy of the awakening morning.The soft colouring of the picture consists of light green, blue-blue, yellow, dark brown tones.Then a conversation is held on the content of the picture: What is this picture about? Who is in the centre of the picture?How are a mother and her child depicted? What feelings did the artist express?Do you like the image of a young mother created by R. Akhmedov?Did the artist manage to convey the freshness and beauty of a young woman bending over her baby?What colours does the artist use to awaken in us a light, joyful mood when perceiving this work?What impression did the painting make on you?Why do you think the painting is called “Morning. Motherhood"?In what details of the picture is the national (Uzbek) flavour manifested?In the next lesson, the attention of students is drawn to another picture by R. Akhmedov "Mother's Meditation".

It was not by chance that the artist's thoughts turned to the images of women, to those who, during the war years, carried on their shoulders the main burden of rear services and collective farm work.The artist's idea of an Uzbek woman, her spiritual beauty, inner strength, humanity, dignity was embodied in the painting "Mother's Thought".A student prepared in advance tells the story of the painting: In the summer of 1956, Rakhim Akhmedov spends in the mountain town of Burchmulla, lives in the house of an old single woman.

In the afternoon he leaves to write sketches, and on long summer evenings, over a bowl of tea, he has leisurely conversations with the hostess.An old woman tells about herself, and a heart-pounding, tragic story is revealed to Rakhim ... During the war, her husband and two sons were killed. It seemed that great grief could not be overcome.But work, people helped me to survive.

Old age has come, and loneliness. “I did not notice,” Rakhim recalls, “how I fell in love with this woman, I fell in love like a mother” [3].

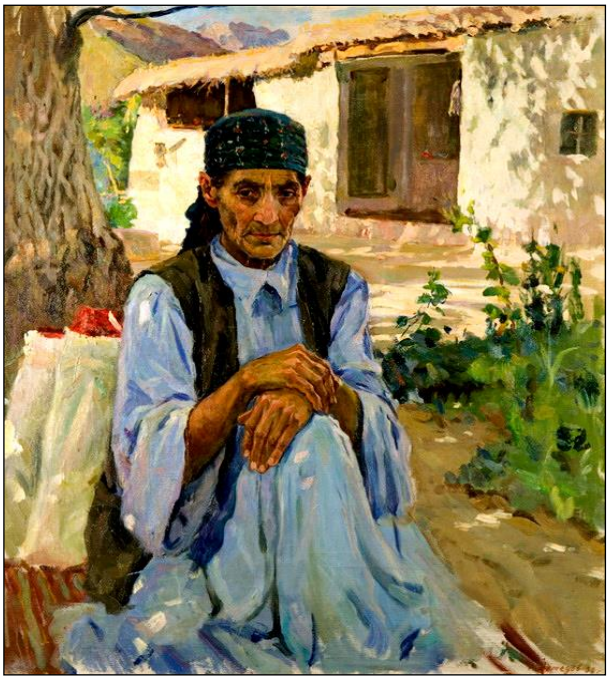

Figure 1 R. Akhmedov. Thought

This is followed by a conversation with the class on the following questions: Who is depicted in the picture? How is an old woman, a mother, who lost both her husband and sons at the front, is depicted? Pay attention to her portrait: what is her face, eyes, mouth, cheeks, what are the hands of the woman, what is the figure, the posture? What about the character of this mother? Did grief suppress her, how did she remain firm and courageous? How does the artist emphasize this woman's will to live? (Note the proud posture of the old woman and the crooked old tree. What did the artist want to emphasize with this comparison?) How does this picture, the image of your mother, make you feel? Using reference words and expressions, the students compose a description of the painting: The painting depicts a woman immersed in her thoughts. She has a sad face, large light eyes, brown shadows under them, a compressed mouth, sunken cheeks. Tired hands lie wearily on their knees. In the centre of the picture is the figure of a woman, she is pushed forward, which emphasizes her scale. The erect posture of the figure, a posture typical for an elderly Uzbek woman, conveys a feeling of inflexibility and firmness.

Figure 2 А.Абдуллаев. Большая семья

This is emphasized by the comparison with the curved trunk of an old tree. Further, the students recall that the fate of the heroine of R. Akhmedov's painting is similar to the fate of the heroine of Ch. Aitmatov's story “Mother's Field”, the Kirghiz collective farmer Tolgonai, who lost her beloved husband and sons in the war, but despite all the troubles she did not break down, did not lose heart. Further, they formulate the conclusion that the picture of R. Akhmedov for them is all the mothers of the Motherland; these are the women of Uzbekistan who, during the Second World War, performed their patriotic, international, simply human duty, adopting children who lost their parents on the military roads. They remember the noble deed of Bakhrikhon Akramova and her husband, the blacksmith Shaakhmed Shamakhmudov, who accepted fourteen boys and girls of different nationalities into their home.

A poem by the Uzbek poet Gafur Gulyam "You are not an orphan!" “Let us bow to the woman, let us bow to the one who will tirelessly give birth to great ones! Aristotle, her son, and Firdavsiy, and sweet as honey, Saadi, and Omar Khayyam, Iskander and the blind Homer - these are all her children, and she brought everyone into the world by the hand, when they were no taller than a tulip - all the pride of the world - from mothers! " (M. Gorky), “Without the sun, flowers do not bloom, without love there is no happiness, without women there is no love, without a mother there is no poet or hero” (M. Gorky).

Further, in continuation of the lesson - pride for the native land, for the ancient culture of his people quotes from the hadiths of the Prophet Muhammad: First bow to your mother, again and again, and then to your father.Anyone who wants to go to heaven must receive the blessing of the mother.

And here they recall Odil Yokubov's work “Everything will return to normal”, which tells that a son who made a pilgrimage to Mecca and returned to his homeland must first come to his mother and bow to her.

CONCLUSION

Opening the world of beauty to a child, making him sensitive to the beautiful and teaching him to appreciate the beauty and create beauty with his own hands is not easy and not easy, but necessary.It is necessary to answer to raise and educate children capable of familiarizing with folk art, mastering the picturesque paintings of artists with its imagery are the conductors of the living tradition of art.

DOPING AND STIMULANTS IN SPORTS: A MENACE AND THREAT

ABSTRACT

Doping in competitive sports is when an athlete uses a banned drug to enhance their performance, such as those found in performance-enhancing medicines. Doping is a term used by organisations charged with monitoring sports competitions. The International Olympic Committee for example, forbids athletes from taking performance-enhancing drugs because of this. Deliberate attempts by athletes (or sports programmes) to evade detection are exacerbated by overt dishonesty and cheating. A lengthy history of doping in sports goes all the way back to the beginning of the sport itself. Recently, the use of performance-enhancing substances in baseball and cycling has been a topic of discussion, although views about these problems have changed significantly over time depending on where you live. For many years, governments and sporting organisations have strictly controlled the use of performance-enhancing drugs and chemicals in sports. As a result of health concerns, equality of opportunity for athletes, and the public relations benefit of drug-free sports, it was decided to ban the use of performance-enhancing substances. Anti-doping authorities argue that using performance-enhancing drugs goes against the "spirit of sport."

KEYWORDS: *Doping in Sports, Use of Drugs in Sports, Stimulants by Sportspersons.*

INTRODUCTION

Drug usage in sports has a long history, dating back to the birth of the sport itself. Athletes and soldiers who were chosen because of their physical fitness were given special diets and therapies to assist them gain muscle mass in ancient times. A combination called "butotens," according to Scandinavian legend, might make Berserkers stronger, but at the risk of becoming insane. The Amanita muscaria mushroom has been implicated as the source of the combination, although this has been refuted.

There have been allegations of doping in the ancient Greek Olympics. Herbal infusions were used by ancient Roman athletes before chariot races, since chariot racing had become a significant aspect of Roman society.

Another example from the 19th century is Abraham Wood, a competitor in a 24-hour walking competition in Britain, who claimed to have taken laudanum (which includes opiates) to keep him awake. Agricultural Hall in Islington, London, in April 1877, walking races extended to 800 kilometres (500 mi). The next year, the distance was increased to 840 kilometres (520 mi).

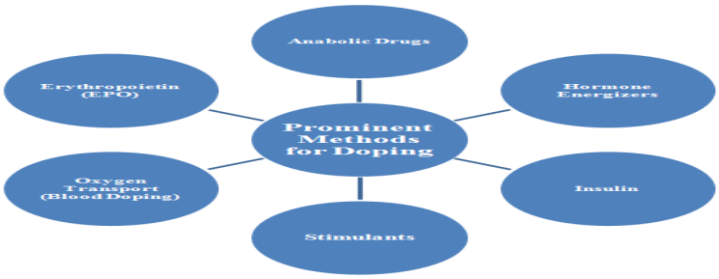

Figure 1: Methods of Doping in Sports

Even while knowing that a person can travel 520 miles in 138 hours and make it through a week on a sliver of sleep may be useful in certain situations, we fail to see how this talent could be put to good use for anybody, or what would be achieved by repeatedly repeating the information.

However, the event was a huge success, drawing in an average of 20,000 people each day. When the concept was well-received, the organisers began holding similar events for bikers.

"A weary pedestrian just sits down; a fatigued biker falls off and may drag others down with him. They are far more prone to suffer in public. That seems like a lot more fun "'s a good place to start.

Six-day cycling races sparked interest on both sides of the Atlantic, drawing large audiences in both countries. To add insult to injury, as more people paid their admission fees, so rewards might be larger, and riders would have more of an incentive to ride as long as possible by staying awake—or being kept awake—to do so. Soigneurs (the French term for "healers"), assistants similar to boxing seconds, countered their weariness. Nitroglycerine, a medication intended to stimulate the heart after a heart attack and which was credited with helping riders' breathing, was one of the therapies they provided. Rider fatigue and/or medications may have caused hallucinations. According to Major Taylor, who declined to continue the race because a knife-wielding pursuer was following him around the ring, he couldn't carry on with safety.

The public reacted negatively to any kind of trial, whether it was a solitary race or a team competition. According to one account:

A sporting event in which the competitors 'get weird' in their minds and stretch their abilities to the point where their faces turn ugly from the tortures they are subjected to is not sport, it is cruelty. According to eyewitness accounts of this bizarre show, several of the cyclists went momentarily crazy during the competition... To get the racers back in shape, it will take days or even weeks of rest, and some of them may never fully recover from the stress.

During the mid-20th century, a physician for the United States weightlifting team, John Ziegler (1917–1983), was the father of anabolic steroids in the United States. In 1954, Ziegler discovered from his Russian colleague that the Soviet weightlifting team's success was attributable to the usage of testosterone as a performance-enhancing substance during his team's world championship trip to Vienna. Ziegler collaborated with the CIBA Pharmaceutical Company on the development of an oral anabolic steroid after concluding that US sportsmen need pharmacological help to stay competitive. In 1960, under the brand name Dianabol, methandrostenolone was introduced to the market. Knud Enemark Jensen, a Danish cyclist, died

in the 100-kilometer (62-mile) event at the 1984 Summer Olympics. Amphetamines and a medication called nicotinyl tartrate were found in his system after his death, according to an autopsy.

According to Max M. Novich, a leading doping expert in the United States, "Trainers of the old school who provided treatments which contained cocaine as their basis stated with confidence that a rider weary after a six-day race would acquire his second breath after ingesting these combinations" 6 day races are "de facto studies studying the physiology of stress as well as the drugs that may relieve fatigue," according to University of Texas Austin professor John Hoberman.

Prevalence

Athletes competing at the 2011 World Athletics Championships confessed to using performance-enhancing drugs (PEDs) at some point in their careers. WADA commissioned a research that found that 44% of athletes had used performance-enhancing drugs in the last year. Despite this, just 0.5% of individuals who were subjected to testing were found to be carriers.

Since Russia's state-sponsored doping programme effectively sanctioned that country's athletes, the entire Russian track and field squad was barred from the 2016 Olympics.

Bob Goldman, a physician, osteopath, and publicist, presented the Goldman conundrum to top athletes, asking whether they would take a medication that guaranteed their success in sports but caused them to die five years later, or not. As in earlier Mirkin studies, around half of the athletes said they would take the medication. However, more recent study by James Connor and colleagues has shown that this figure is considerably lower, with athletes showing acceptance of the issue at a level comparable to the general Australian population.

Substances for Doping

Doping in sports is most often accomplished with one or more of the following substances: Well-known stimulants include things like caffein, cocaine, amphetamine, and modafinil, as well as ephedrine and other similar substances. Despite its reputation as a stimulant, the International Olympic Committee and the World Anti-Doping Agency have not banned caffeine since that year. Most often, anabolic steroids are used to enhance muscular growth and strength. Drugs that enhance enthusiasm while decreasing tiredness are known as stimulants (the second most prevalent kind).

Steroids for anabolism: First discovered in the 1930s, anabolic-androgenic steroids (AAS) are currently being used therapeutically in medicine to promote bone development, increase appetite, speed up puberty in men, and treat chronic degenerative diseases like cancer and AIDS. As a result, anabolic steroids are popular in sports and bodybuilding, where they're utilised to boost performance or physique. On the other hand, there are known adverse effects, including as elevated levels of low-density lipoprotein (LDL), acne, high blood pressure, and liver damage. Supplemental medications may help with some of these side effects.

At the beginning of October 1954, the American weightlifting team travelled to Vienna with a doctor who treated their players, Dr. John Ziegler. There he met a Russian doctor who frequently questioned him, "What are you feeding your boys?" over "a few beers." When Ziegler asked the Russian about it again, he revealed that his own athletes were given the drug. In the United States, Ziegler tested low testosterone dosages on two weightlifters, Jim Park and Yaz Kuzahara as well as on American trainer Bob Hoffman. No training regimen could have given them the results they got without it, but there were consequences. After searching for a medication with no side effects, Ziegler came upon the anabolic steroid methandrostenolone (marketed as Dianabol in the US in 1958) manufactured by Ciba (colloquially known as "d-bol").

International Perspectives

Former U.S. Olympic Committee drug-control administrator Wade Exum handed over documents to Sports Illustrated in 2003 revealing that approximately 100 American athletes failed drug tests between 1988 and 2000, arguing that they should have been barred from competing in the Olympics but were still allowed to compete. These athletes included Carl Lewis, Joe DeLoach and Floyd Heard. Exum attempted to use the papers in a lawsuit against the USOC before revealing them to Sports Illustrated, alleging racial discrimination, wrongful termination, and a cover-up of the failed tests. His lawsuit was dismissed outright by the Denver Federal Court due to a dearth of evidence. It was deemed "baseless" since he was in charge of screening the organization's anti-doping programme and confirming that the athletes had been approved in accordance with regulations, as stated by the USOC.

At the 1988 Olympics trials, Carl Lewis tested positive for minimal quantities of prohibited stimulants pseudoephedrine, phenylpropanolamine and ethanol three times, according to Exum's records. Cold medications often include bronchodilators as well. His case might have resulted in his being disqualified from the Olympics and banned from participation for a period of six months under the regulations. The total stimulant levels were found to be 2 parts per million, 4 parts per million, and 6 parts per million in the various tests. Lewis stood by his storey, saying he had inadvertently ingested the illegal drugs. Following an examination of the supplements he had taken to support his claims, the USOC approved his claim of unintentional usage after discovering that one of the pills he had taken included "Ma huang," the Chinese term for Ephedra (ephedrine is known to help weight-loss). Joe DeLoach and Floyd Heard, both members of the Santa Monica Track Club, were also tested positive for prohibited stimulants but were allowed to participate nonetheless. For a short time in 1988, 6 ppm of Lewis' stimulant concentration was considered positive; however, that is no longer the case. Because of this, the allowable concentrations of ephedrine and other chemicals have been increased from five to 10 parts per million. Positive tests at levels less than 10 ppm were subject to additional inquiry but not an instant suspension, according to IOC regulations at the time. This is what you'd observe in someone taking cold or allergy medications, according to Neal Benowitz, an expert on ephedrine and other stimulants at UC San Francisco, who concurred that "These [levels] are unlikely to have any impact on performance." IAAF recognised that the USOC did indeed follow the proper procedures in dealing with eight positive results for low concentrations of ephedrine and ephedrine-related substances in 1988 Olympic Trials after hearing from Exum's testimony. Also in 1988, the federation conducted a review of the relevant documents without disclosing who the athletes were and found that "the medical committee felt satisfied, on the basis of the information received, that the cases had been properly concluded by the USOC as 'negative cases' in accordance with the rules and regulations in place at the time and no further action was taken.

Eight of the United States' gold medals at the Olympics were revoked because of drug offences. Athletes sanctioned for doping violations acted independently of the US government or the US Olympic Committee (USOC). For example, the United States Olympic Committee (USOC) in 2001 acknowledged swimmer Rick DeMont's gold medal performance from the 1972 Summer Olympics, but only the International Olympic Committee (IOC) can restore his medal, and the IOC has refused to do so as of 2017. DeMont had previously won the gold medal in the 400 metre sprint with a time of 4:00.26. It took the IOC until after the race to take away his gold medal because he tested positive for the prohibited drug ephedrine in his prescription asthma medicine, Marax, during the post-race urine. After a positive test in the 400-meter freestyle final, he was disqualified from competing in any other events at the 1972 Olympics, including the 1,500-meter freestyle, where he held the world record at the time. This cost him a shot at several medals. The USOC failed to get clearance from the IOC's medical commission for DeMont's

asthma medicines before the Olympics, despite the fact that he had disclosed them on his medical disclosure papers.

FIFA believes education and prevention, together with ongoing testing both within and outside of competition, are critical to ensuring that high-profile sporting events are free of performance-enhancing substances. As a result, there have been very few instances of doping in football. A joint statement signed by FIFA officials and team doctors says that they support regular blood testing to look for signs of blood doping before any FIFA World Cup.

There was an introduction of the biological passport in 2014 at the FIFA World Cup; the Swiss Laboratory for Doping Analyses examines blood and urine samples taken from all players before to participation and from two players per team and each match.

The UFC launched a year-round random drug testing programme in December of that year. Despite the fact that random testing was difficult for the organisation, fighters who tested positive had to be removed from bouts, which hurt fight cards and therefore pay-per-view sales. Fights would have to be cancelled if the UFC couldn't locate a substitute. Since the program's inception, approximately 31% of UFC competitors who have been randomly tested for the use of performance-enhancing substances have failed. In other words, for every sixteen random screens, there are around five failed tests.

Beginning in July 2015, the UFC has pushed all commissions to require drug testing before every event. Lorenzo Feritta, who at the time was one of the presidents of the UFC, said, "We want 100 percent of the fighters tested the night they compete". As a result, in addition to the standard pre-fight drug testing, the UFC now tests athletes who are scheduled to participate in title bouts on fight night. Tests for performance-enhancing substances will be conducted on both urine and blood samples collected 'out of competition,' as well as at predetermined intervals. The UFC also stated that before being given a contract with the organisation, all prospective UFC signees would be subject to a required pre-contract test for performance-enhancing substances.

Sports that need stamina and perseverance: In a variety of sports, the use of performance-enhancing chemicals has grown to be a growing issue. Any chemical or drug that provides an athlete an unfair edge over a "clean" athlete qualifies as performance-enhancing drug use. The prohibition of these substances encourages fair play and equality for all athletes. Since it gave swimmers an unfair advantage via hydrodynamics, the wearing of "the suit" during competition was outlawed internationally. Athletes' medication regimens vary significantly depending on the sport's performance requirements.

Endurance athletes use erythropoietin (EPO) to boost their red blood cell count, which results in more oxygen-rich blood and a greater VO2 max. In endurance sports like swimming, long-distance running, cycling, rowing, and cross-country skiing, a person's VO2 max is strongly linked with their performance. EPO has lately become popular among endurance athletes because of its potency and poor detectability compared to other doping techniques like blood transfusion. Although EPO was extensively used by sportsmen in the 1990s, there was no method to test for the drug directly until 2002 since there was no specialised screening procedure for testing athletes. Blood and urine tests are used to check for EPO levels in Olympic athletes. The risk of doping in certain endurance sports may be reduced by following strict rules and restrictions.

When it comes to doping, elite athletes are driven by financial competition, which is different from recreational athletes' interests, elite athletes have different incentives. The pressure to physically perform is a recurring element in these reasons. A survey of 101 people found that 86% said that the possibility for athletic success impacted their usage of performance-enhancing drugs, 74% said that the economic element was important, and 30% said that self-confidence and

social recognition played a role in their decision. It was shown that athletes utilised performance-enhancing pharmaceuticals for therapeutic reasons in another research of 40 individuals in order to be competitive in top sports for the monetary incentives associated with them. The societal and physical demands to have a particular body type are often intertwined. Muscle dysmorphia is a condition in which a person desires a more muscular appearance for practical and self-esteem reasons. Preventing nutritional deficiency and bolstering the immune system are the most common reasons why athletes use supplements. All of these aspects are geared at making the body more efficient so that it can function better.

Psychiatric factors

Doping in sports requires consideration of a variety of factors, including psychology. Recognizing and participating in doping despite the health dangers becomes a behavioural problem for the athlete. To put it another way, many take it because they believe it would make them feel invincible. Because they believe the performance-enhancing medication provides the outcomes, the people are driven only by their own egos and the drug's promise of increased performance. There are three distinct psychological factors that drive someone to dope: social cognition, stress and strain, and addiction, according to a research on health psychology conducted by Quirk the "doping dilemma" occurs when social and physical constraints drive athletes to feel that they must use performance-enhancing substances to keep up with their peers.

Legal Perspectives on Doping

• The World Anti-Doping Agency was established in 1999 after an initiative by the International Olympic Committee to combat doping in sports. The International Olympic Committee (IOC) established WADA in the wake of the 1998 cycling doping crisis to promote, coordinate, and monitor the fight against doping in sports. Montreal, Canada, is home to WADA's main office. With this power, WADA may conduct dope tests and decide which drugs are prohibited.

• Play Asterisk Free, an anti-steroid campaign targeted at teenagers, was launched in February 2011 by the US Olympic Committee and the Ad Council. The "Don't Be An Asterisk!" campaign was originally introduced in 2008 with that moniker.

Cyclist Lance Armstrong was found to have used performance-enhancing drugs by the United States Anti-Doping Agency (USADA). "...scientific data and laboratory test findings further show the usage, possession and distribution of performance-enhancing substances," said USADA CEO Travis T. Tygart.

S. 1829, the Steroid Trafficking Act of 1989, was proposed by US Senator Joseph Biden on November 1, 1989. The act's goal was straightforward: It would "To further limit the use of anabolic steroids, the Controlled Substances Act should be amended. The bill would make anabolic steroids a Schedule II restricted drug, making them more difficult to get legally "'s a good place to start. p. 282) of the Senate Judiciary Committee's report.

The athlete will be requested to give a urine sample as part of the approved doping control procedures. The sample will be split in half and stored in sealed containers carrying the same unique identifying number and designation as A- and B-samples, respectively. The findings of a confirmation test on sample A showed that the athlete's B-sample also tested positive for a banned drug, therefore an examination of the B-sample was ordered. Test results are regarded positive if the B-sample test results match the A-sample findings; otherwise, they are termed negatie if they differ. The individual's security is ensured by this validation procedure.

An erythropoietin recombinant blood test may identify the use of illicit performance-enhancing substances by measuring markers that change when the drug is used.

1. Hematocrit

2. Reticulocytes

3. Iron Levels

Combustion-IRMS Gas Chromatography

Any deviations from the standard in the isotopic composition of an organic molecule may be detected using gas chromatography-combustion-IRMS. When synthetic testosterone is taken, the T/E level raises abnormally, and this test helps determine whether that's the case.

Athletes may make themselves inaccessible during testing times to avoid getting examined. Athletes are required to disclose their whereabouts at all times to help minimise this. The same as rejecting a drug test is deemed a doping violation if planned doping tests could not be performed because the athlete could not be located three times a year. Athletes are required to record their whereabouts through an app and a website called ADAMS.

Donald Berry has raised concerns about the validity of several standardised exams in an essay published in Nature. According to Berry's paper and an accompanying editorial, these concerns include:

In his argument, it is claimed that anti-doping authorities have not sufficiently specified and publicised how they arrived at the criteria used to decide whether or not a test result is positive. [...] Individual laboratories must validate these detection limits in bigger groups, including both known dopers and non-doers, under blinding circumstances that mirror what occurs during competition, according to Berry. An arbitrary test for which the percentage of false positives and false negatives can never be determined, according to Nature, is what the editorial concludes with. According to a wired article by G. Pascal Zachary, allowing performance-enhancing drugs and genetic modifications would fulfil society's need for übermenschen and restore public interest in sports.

CONCLUSION

Athletes are held to moral standards by society but do not live up to those norms themselves, say sports researcher Verner Moller. According to an article written by Fox Sports' Jen Floyd Engel, "We live in a culture that relies heavily on pharmaceuticals. We live in a world where shortcuts are taken, where things are faked or improved, and yet we continue to push the narrative that sports have devolved into a corrupt cabal of corruption. Athletes are just doing what so many of us do every day of our lives: celebrating and watching." Transfusing blood cells is not permitted, but other ways of increasing the number of blood cells, such as hypobaric chambers, are acceptable, according to sociologist Ellis Cashmore. Similar arguments have been put forward by other academics. Individual sports governing organisations' anti-doping rules may be at odds with state and municipal legislation. When a federal judge decided that municipal labour rules trumped the NFL's anti-doping system, the NFL found itself unable to discipline players who tested positive for prohibited drugs. The NFL Players Association lent their support to the cause. Athletes who use performance-enhancing drugs (PEDs) may face sanctions from both their local and national regulatory bodies. Depending on where you live, anabolic steroids may or may not be allowed in your nation. If Bill S-209 is passed, fighters who are caught taking performance-enhancing substances in mixed martial arts contests (such as the UFC) may be subject to civil and criminal prosecution. Athletics may be given a therapeutic use exemption if they need the use of an otherwise illegal drug to address a medical ailment.

ABSTRACT

When heavy metals are exposed to stress, they declinate into molecular oxygens, releasing highly reactive transitional chemical products such as hydrogen peroxide (H2O2), superoxide radicals, and hydroxyl radicals, all of which are classified as reactive oxygens. Heavy metal pollution is a serious global environmental problem because it disrupts plant growth and causes genetic dissimilarity. Heavy metals, both necessary and non-essential, have similar fatal effects on plants, such as poor biomass accretion, chlorosis, growth inhibition, photosynthetic inhibition, altered water balance and nutrient integration, and senescence, which ultimately leads to plant disease. The goal of the research was to look at the impacts of heavy metals on plants and biological systems, as well as remediation techniques. Precipitation, Biosorption, Ion Exchange, and Filtration are all efficient techniques for overcoming this issue, but they are not cost-effective. Phytoremediation was shown to be the most efficient and cost-effective method in this respect. Although bioremediation seems to be the greatest option, it does have certain drawbacks. In order to use this technique effectively, a longer study must be accompanied in order to decrease the constraint.

KEYWORDS:*Agriculture, Anthropogenic, Metals, Pollution, Soil.*

1. INTRODUCTION

Human usage and management of water and soil resources have impacted the growth, survival, degradation, and revival of anthropoid advancements supported by agriculture. Soil and water are essential natural resources for the domesticated food production system based on plants and animals. Despite the fact that soil is often referred to as the "productive substrate," not all soils are suitable for crop development. In ideal agricultural soils, mineral inputs, soil organic matter, air, and water are all present. The balanced contributions of these components enable water retention and drainage, root zone oxygen, nutrition to assist yield growth, and plant physiological care. The circulation of soil components in a particular soil is influenced by five factors: parental material, time, weather, species, and landscape[1].

Each component has a direct and overlapping impact on the suitability of a soil for agricultural use. Agriculture disrupts the natural cycle of nutrients in soil. Plant nutrients may be extracted from the soil using precision agronomy and harvesting of crops for human and animal use. To maintain soil richness for sufficient yield harvests, soil amendments are generally required. To improve soil fertility, early hominids used animal dung, charcoals, ashes, and lime in their arenas (CaCO3). Farmers now employ a range of soil additives, including inorganic compound manures and carbon-based sources of nutrients, such as manure/compost, to enhance soil richness, which has resulted in an oversupply of primary macronutrients. Excess nutrients, especially nitrogen and phosphorus, may pollute the soil and groundwater when they are transferred from agricultural areas through surface runoff or leaching[2].

Soil is an important component that receives a significant amount of pollutants each year from a variety of sources. Soil, in general, serves as a natural barrier by controlling the movement of chemical components and chemicals into the atmosphere, as well as a sink for substance pollutants. Heavy metals are usually thought to be naturally occurring substances, although they are found in large amounts in certain ecological areas as a result of human activity. As a consequence, the environment's ability to replace lifecycles is damaged, posing a threat to human, animal, and plant health. This is due to the non-degradability of heavy metals, which promotes bioaccumulation in food chain. In a broad range of biological patterns, heavy metals may be found in both degraded and uncontaminated soil coverings. Because heavy metals cannot be tarnished or removed, they accumulate in soils, water, and residues. Heavy metals in soils may also be formed naturally as a result of human activity. Atmospheric emissions from volcanoes, movement of mainland soils, and weathering of metal-supplemented rocks are examples of natural bases[3].

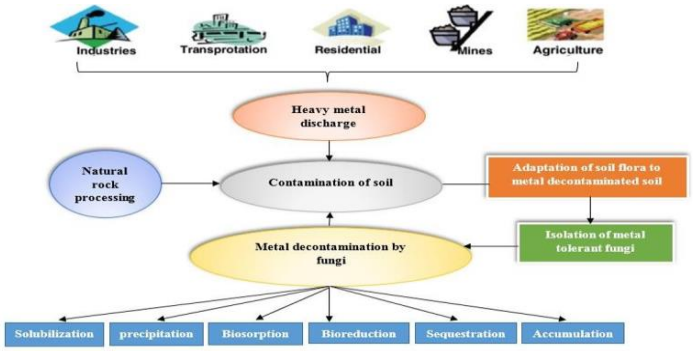

Figure 1: Representation of Heavy Metal Pollution Sources and the Approved Approaches for Metal Refinement.

Figure 1 represents Heavy Metal Pollution Sources and the Approved Approaches for Metal Refinement.Adulteration of agricultural and forestry soils with trace metals and metalloids has been a major source of worry throughout history. Metals in agricultural soils may enter food

chains, increasing human exposure and risk (both cancer-causing and noncarcinogenic hazards), while metals in woods are mainly a danger to porewater supplies, environmental risk, and woodland health. Metalloid and trace metal pollution in agricultural and forest soils has been a significant issue for decades. Due to rapid automation in emerging nations, the global world's excessive use of metals and manufactured chemicals, coupled with inadequate environmental management, resulted in widespread contamination. Heavy metal contamination in agricultural soils has sparked concern in recent years about the risk of direct consumption, bioaccumulation via the food chain, and ecological system effects to human health. Heavy metals such as copper, zinc, and manganese, as well as unneeded heavy metals such as cadmium, chromium, manganese, and lead, are the most hazardous to humans and marine life.

The presence of metallic elements in soils is a major issue since they accumulate in food chains, causing damage to the whole environment. Organic pollutants are biodegradable, but the presence of heavy metals in the atmosphere reduces the biodegradable frequency, thus doubling the emissions, i.e. organic pollutants and heavy metals. Heavy metals endanger people, animals, plants, and natural ecosystems in a number of ways. Variations in soil pH, penetrability, pigment, and usual interaction, as well as uninterrupted ingestion, plant adsorption, food-cycle, drinking contaminated marine, and changes in soil pH, penetrability, pigment, and usual interaction, all have an impact on soil value[4].

1.1 Heavy Metal Bases:

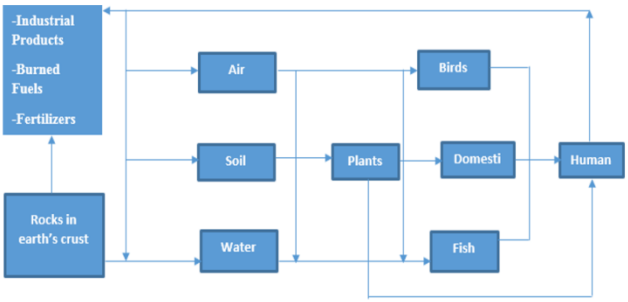

Figure 2: Representation of Metallic Element and Their Cycling In the Soil-Water-Air Organism Ecosystem.

Figure 2 represents Metallic Element and Their Cycling in the Soil-Water-Air Organism Ecosystem.

- **Natural Processes:**

Natural heavy metal emissions occur as a result of a variety of environmental factors. Such pollutants include volcanic eruptions, sea-salt sprigs, forest fires, rock cracking, biogenic source, and wind-borne soil particles. Metals may be released from their usual spheres and into various environmental sections as a result of natural weathering processes. Heavy metals include hydro-oxides, oxides, sulphides, sulphates, phosphates, and carbon-based compounds. Even though residues of the above-mentioned heavy metals have been discovered in humans and other animals, they continue to cause serious health issues[3].

- **Anthropogenic Processes (Anthropogenic Processes):**

Heavy metal anthropogenic activities have been shown to go beyond natural metal variations. Metals often detected in wind-blown dusts come from industrial locations. Smelting, which releases arsenic, copper, and insecticides, which releases arsenic; and the flickering of fossil energies, which releases nickel, mercury, and extra heavy metallic elements, are all significant anthropogenic bases that knowingly contribute to heavy metal adulteration in the atmosphere. Because of everyday production of products to meet the needs of the large population,

anthropological activities have been observed to pay greater attention to environmental pollution[4].

1.2 Mechanisms of Remediating Heavy Metals:

Acid mine water treatment techniques produce high density slush that is dissimilar, making disposal problematic due to a variety of metals, metalloids, and anionic constituents. As a consequence, current study has concentrated on chemical kinds found in Acid Mine Drainage (AMD) and subordinate slush. This helps to recover limited resources while also making sludge treatment and disposal simpler and safer, lowering environmental impact. Metal-laden waste is disposed of in landfills and leftover retention tarns, contaminating surface and subsurface water sources in the process. It may also indicate the presence of soil contamination, which decreases efficiency. Heavy metal clean-up methods should be given suitable and comprehensive attention in order to preserve humanoid well-being, floras, faunas, soil, and other habitat sections. The bulk of physical and chemical metallic element clean-up techniques need large amounts of sludge processing, destroy ecosystems, and are very expensive[5].

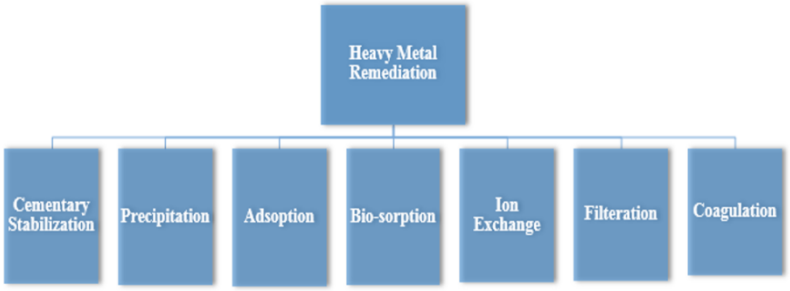

Figure 3: Representation of various methods to remove heavy metals from agricultural soil.

- **Precipitation:**

Various alkalescent chemical reactants have been employed to neutralize AMD (Acid-Mine-Drainage) throughout the years in order to increase the pH and, as a consequence, precipitate and recover the metals. The most common alkalescent reactants utilized for successive recovery of reserves resources from AMD and magnesium hydroxide (Mg(OH)2) are caustic potash (NaOH), clastic rock (CaCO3), burntlime (CaO), sodium carbonate (Na2CO3), and calcium hydroxide (Ca(OH)2)[6].

- **Adsorption:**

Because of its instability and elution capabilities, suraface assimilation is regarded the most efficient and economically viable option for eliminating metals from liquid blends. With highly concentrated solutions, surface assimilation is unsuccessful because the adsorptive rapidly becomes saturated with the adsorbate. It's only useful for very dilute mixes, it takes a long time to renew, and it doesn't discriminate between metals when it comes to attenuation[7].

- **Exchange of Ions:**

Between a solid substrate and a soil solution, this is often referred to as ion exchange. Clay and mastics with an increased atomic interchange potential are often used to approve alloys made from liquid blends. This method, however, is time intensive and only works for a limited number of metal concentrations in the combination. Heat and alkalinity affect this arrangement as well.

- **Biosorption:**

Biosorbents have many benefits, including accessibility, performance, and capacity. This is a basic and easy process. It's simple to regenerate, which makes it attractive. However, if the

feedstuff blend concentration is too high, the progression will rapidly outstretch, preventing advance impurity removal.

- **Membrane Technologies:**

When the water includes a significant concentration of pollutants, sheath equipment for acid mine drainage recovery is especially effective. Either assisted diffusion or reverse osmosis are used in this process. Some of the membranes used in mine water treatment filtration include ultrafiltration, nanofiltration, diffusion, microfiltration, and element percolation.

1.3 Challenges in The Phytomining Of Metallic Elements Polluted Soil:

Several biological, physical, and biochemical techniques have been employed to remove heavy metals from the soil during the last two centuries. These approaches, however, have significant drawbacks. They need a lot of time and effort, as well as a lot of disturbance in the native soil microbiota and constant changes in the physio-chemical characteristics of the soil. Phytoremediation technique is given unique attention amongst different perspectives to repair the heavy metal contaminated soil undisturbed. Phytomining is a method that uses natural or genetically engineered plants to remove dangerous chemicals from the environment, such as radioactive elements, fungicides, polychloroterphenyl and polynuclear pungent natural gas, and convert them to safe combinations. The emphasis of phytomining is divided into three layers: plant-centered element removal with monetary advantages, threat reduction, and maintainable soil oversight, in which phytoremediation gradually increases soil richness, allowing crop development to be tracked. High biomass fabrication and fast-budding plants, such as poplar, jatropha, and willow, are being used for the twin aim of energy generation and phytomining in the accumulation. Phytomining is a solar-powered, recyclable machine that has a good reputation in the community. In the near future, phytoextraction of metallic elements is expected to be a cost-effective equipment for agromining of metallic elements. Phytostabilization, phytoextraction, rhizofiltration, phytoevaporation, and rhizodegradation are some of the accepted equipment used in modern phytomining.

2. LITERATURE REVIEW

In established and underdeveloped agriculture, A N Ganeshamurthy et al. discuss the ecological danger of metallic element pollution in water, plants, and soil. Since the invention, the percentage of Indians living in towns and developed regions has increased to 27%. Despite restricted regulations and restrictions, underdeveloped agribusinesses are operated on a large scale in many developed regions throughout the globe. Non-degradable pollutants introduced into the system by human activities, such as metallic elements in soil, water, air, and crops, cause more concern since they have a tendency to bio-accumulate. Metallic element poisoning has wreaked havoc on humanity in the past, destabilizing intellect and causing embarrassing conduct. The body suffers from a shortage of important elements such as Cu, Zn, and others as a result of these pathogenic elements. With current level knowledge, a long-term and assured technique to block the entry of metallic elements into the food cycle is challenging. There are a number of options for reducing the outcome's concentration. Crop lands used in a different manner, which is indirectly eaten by people and animals, is a superior tonic for retaining element entrance into the food chain. There are many ecological regulations in India that regulate water, air, soil, and trash. Governmental foundations are built on the belief that a regulatory paradigm is sufficient. Regulatory mechanisms may not be in place in all instances, but they are essential derivators to complement other methods by putting a “cap” on the degree of deprivation that is informally acceptable, as well as allowing for alternative, cleaner, and appropriate replacements to be “feasible[8].”

Shalini Arora et al. discussed soil analysis and its potentially harmful impacts on human health. The study of the environment has been going on for a long time, and the molecular structure of naturally occurring topsoil has been changing through time in response to the ecological conditions of the environment. This percentage is the deciding element of soil richness because when the soil arrangement changes, the richness and quality of the soil degrades quickly. Long-term, low-level exposure to basic contaminants in the atmosphere often results in metallic poisoning. Exposure to hazardous metallic elements has been linked to a number of long-term illnesses and may result in a wide range of health problems. Urban soil receives various contributions of metallic elements from a variety of moving and stationary sources, such as vehicular traffic, power generation facilities, waste incineration, and resuspension of surrounding polluted top soil, and thus plays a significant role in contamination in developed areas. Because roadside topsoil is more polluted than any other location, such as grounds or a farm home, the percentage of the composition of the top soil varies in various regions of the atmosphere. Due to significant growth in automobiles and industry, these differences are particularly noticeable in Indian metro areas. As a result, urbanized top soil study is important for determining the source, circulation, and metallic pollution in developed regions[9].Ahmad E et al. discussed Importance of Free-Living Fungi in Heavy Metal Remediation in which they discussed how Heavy metal pollution is one of the world's most serious environmental issues, presenting serious threats to agro-ecosystems. Historically, heavy-metal cleanup methods have been both costly and inconvenient. This book offers thorough, up-to-date coverage of natural, sustainable alternatives to heavy metal removal/detoxification that utilize a broad variety of biological components, resulting in improved crop yields in these soils. Based on a thorough knowledge of metal pollution and the roles of plants and microorganisms in the management of hazardous soils, novel, ecologically friendly, and low-cost solutions are given. The book, written by international specialists, not only offers the essential scientific foundation, but also tackles the difficult issues that must be addressed in order to better comprehend metal toxicity in soils and its treatment via bioremediation[10].

3. DISCUSSION

There is a complicated connection between environmental chemical composition of natural resources and emissions, according to their independent study. Ferrosol sewage sludge is the source of heavy metal's environmental impact.The impacts of heavy metal emissions from different sources on topsoil and flowing water in various regions of the globe, as well as their dominance of pollution or metallic residues. Heavy metals such as chromium, manganese, copper, mercury, and zinc pollute soil, posing serious environmental problems since they are non-essential and detrimental to flora and wildlife, as well as having a direct hazardous effect on human health. Anthropogenic activities such as mining, industrial development, and agronomic practices such as the use of pesticides, fungicides, and composts have lately discharged heavy metals into the topsoil, water, and atmosphere. Through a number of physiological processes, these metallic elements are released into the plant system, affecting plant growth. The absorption of metallic elements into the environment varies according to a variety of factors, and it becomes hazardous when it exceeds acceptable limits. The possible genesis of these components has led to an increasing presence of metallic elements in the environment, whether via direct absorption from contaminated soil, depletion of fully-fledged crops on polluted soils, or drinking waste-water that has infiltrated through these soils. The goal of this study was to look at how heavy metals affect agriculture and how they affect human health, as well as to propose some ways for removing heavy metals from crops and soil. Heavy metal buildup occurs only when vegetal crops are cultivated in a contaminated region with metallic elements, and these metallic elements subsequently enter the food chain. When people consume a metallic element-contaminated root vegetable, they develop a range of severe health issues. These heavy metals have an impact on

soil nutrient status, soil strength, water supplies, and extramarine living organisms, in addition to plants and people.

4. CONCLUSION

By producing different types of garbage and dumping them without proper management, modern lifestyles and industrialization have created countless environmental problems. These trashes contaminate the environment, causing the most critical and fatal impacts on living creatures, jeopardizing their survival. The most hazardous feature of industrial wastes and other trashes is the discharge and buildup of metals, particularly heavy metals. Metallic element contamination of agricultural soils as a result of growth and industrial development is of great concern due to the potential health risk caused by consuming contaminated crops. Vegetables are an important component of the human diet because they provide vital nutrients for optimum health. As a consequence of frequent applications of fertilizers and pesticides, heavy metals have accumulated in plants. The toxicity of heavy metals ingested via contaminated vegetables is a major issue.

However, just a few researches have been conducted to establish the permissible limits of heavy metal music. As a result, it is recommended that trash be processed before being thrown in the environment in order to reduce the sound impacts on the atmosphere by converting them into less hazardous forms. Effective treatments are too costly. The most efficient and cost-effective approach in this respect has been determined to be bioremediation, which entails the use of living organisms to address certain pollution-causing circumstances via effective absorption of pollutants from the desired environment. It has been discovered that phyto-remediation, or the employment of plants to clean up trash, is extremely successful. In addition, a new research on heavy metal exposure in babies, the elderly, and women, especially pregnant women, is required. In addition, strategy and policy are needed to monitor the limits of accretion in vegetables and hyperactive accumulators specified for certain plants.

ABSTRACT

This article covers the main initiatives for wireless fifth Generation networks. The program and project efforts as well as the newest publications are emphasized. A closer investigation is being conducted at a broad range of projects connected with Fifth Generation in the EU. Recent thematic IEEE Communications Magazine Fifth Generation issues, as well as related White Papers from other sources, are limited to literature review. The aim is to explain what Fifth Generation means: what the main issues are and how to address the essential components of the fundamental fifth Generation system concept. The references examined indicate that Fifth Generation needs to provide low latency, extremely reliable communications and wide connection in addition to capacity boosting technologies. The most challenging element in Fifth Generation development will therefore be the creation of a sufficiently flexible system concept platform for effectively integrating and controlling numerous distinct technologies that are suited for diverse applications.

KEYWORDS:*Fifth Generation, Access, Networks, Project, Radio, Spectrum, Technology, Wireless.*

INTRODUCTION

Capacity demand for presently deployed Third Generation and Fourth Generation wireless technologies has been driven by growing internet traffic. Intensive research is currently underway on many fronts towards 5th generation wireless communication networks. In this study, a broad range of European research projects, current literature and Fifth Generation white papers from key players in wireless technology are analyzed to scratch the surfaces of various

Fifth Generation activities. The aim is to help you understand what Fifth Generation is and how different Fifth Generation initiatives are designed to accomplish this[1].

There is currently no one Fifth Generation definition. But the notion that Fifth Generation is simply a mix of various methods, scenarios and case usage rather than a new single technology of broadcasting access is widely accepted. The following lists as technical requirements for current technology (Fourth Generation)[2]:

- thousand times higher mobile data volume per area
- ten to hundred times higher typical user data rate
- ten to hundred times higher number of connected devices
- ten times longer battery life for low power devices
- five times reduced end-to-end latency

The 5th generation Non-Orthogonal Signaling Waveforms project provides a scalable, efficient air interface that gives up the strict constraints of orthogonality and synchronization enforced by previous generation networks. UFMC, Filter Bank, and Generalized Frequency Division Multiplexing are some of the most promising examples of orthogonal frequency division multiplexing in a Fifth Generation context. It covers aspects such as a single frame structure, filters, sparse signal processing, robustness and very low latency transmission, in addition to the multicarrier waveform design itself[3].

Enhanced Multicarrier Technology for Professional Ad-hoc and Cell-Based Communications project provides the channel estimation, equalization, and synchronization capabilities needed for a highly flexible and efficient filter-bank processing. In addition, the viability of multi-carrier filter bank-based methods such as relays, multi-hops, cooperative systems in certain settings where synchronization is difficult to maintain is assessed[4].

Fig. 1: The Launch of Commercial 5G in India Has the Potential to Increase the Median Download Speed By Up To 10 Times Compared To the Download Speeds Offered Currently By Fourth Generation- Long Term Evolution (LTE) Networks.

Physical Layer Wireless Security project aims to enhance privacy via security and secrecy coding in physical layer on wireless networks. Confidential radio waveforms and access methods in real experimental Wi-Fi settings and LTE simulation scenarios are created and assessed[5].

Full-Duplex Radios for Local Access idea relies on radio transceiver technology that simultaneously utilizes the same frequency as the carrier for transmission and reception. This new paradigm of transmission may enhance connection significantly and provide new methods of flexible spectrum use and networking.

Connectivity management for Energy Optimized Wireless Dense networks project aims at extremely dense heterogeneous wireless/wired backhaul integrated access networks. The goals are to provide density-related capacity when required, to optimize MAC mechanisms for various settings, to enable traffic-proportionate energy consumption and to guarantee user experience via intelligent connection management systems.

Dense Cooperative Wireless Cloud Network in the solution of wireless communications issues in highly interfering ad hoc networks, Project utilizes the paradigm virtual relay-based wireless cloud that offers a simple and unambiguous interface to the terminals.

Interworking Design of an Open Access and Backhaul Network Architecture for Small Cells based on Cloud Networks project will use a centralized Radio Access Network paradigm with a cloud infrastructure based open IT platform. Access and backhaul is designed and improved in combination.

Responses to the following questions are requested by Distributed Computing, Storage and Resourcing for Collaborative Femtocells project: What kind of communications/computing technologies are required to converge total women's network and cloud computing infrastructure?

How much can the proposed femto-cloud methods improve the spectral/energy/service efficiency? Femtocell-based wireless technologies for isolated rural communities in developing countries use the new wireless access (Third Generation or Fourth Generation femtocells) and heterogeneous outdoor backhaul technologies for the development of cost-effective and technologically sustainable rural environments, using the long-distance WiFi, WiMAX and VSAT.

A large-scale integration-based industry led effort is beyond 2020 Heterogeneous wireless networks with Millimeter-Wave Small Cell Access and Backhauling. It investigates and demonstrates key technologies and characteristics to enable the integration of future heterogeneous networks of millimeter waves of small cells. In particular, the project is interested in networking features and algorithms as well as integrated radio and antenna technologies.

Advanced Dynamic spectrum Fifth Generation mobile networks Employing Licensed shared access. The study subject under the licensed shared access paradigm is explored in the project's primary aim:

- guaranteeing quality of services for customers of all participating networks of spectrum sharing
- reducing overall energy consumption of lens networks
- dynamic, optimum allocation of spectral and power resources at timeframe from seconds to even milliseconds

Spectrum Overlay via aggregation of heterogeneous Dispersed bands the main aim of the research is to efficiently integrate heterogeneous and heterogeneous Radio Access Technologies non-continuous scattered spectrum bands to offer a new overlay technique.

Cognitive Radio Standardization effort Coordination activities coordinate and support existing and future FP7 projects. Coordination activities they adopt a targeted approach and plan for standardization to exploit their cognitive radio and dynamic spectrum discoveries.

Cognitive Radio for Satellite Communications project researches develops and proves the suitable cognitive radio techniques in satellite networks, including dynamic spectrum sharing. The goal is to show that their future disadvantage will surpass new economic possibilities and benefits of flexible spectrum usage.

Self-Management for Unified Heterogeneous Radio Access Networks objectives of the project are to create multi-radio access technology, including SON functionalities and the creation of an integrated SON management system.

Massive MIMO for Efficient Transmission aim of the project is to move MIMO from a highly promising theoretical concept to a practical level utilizing new low-cost yet flexible technologies.

High capacity network Architecture with Remote radio heads & parasitic antenna arrays Project aims to provide multi-antenna distributed wireless access by combining radio remote heads technology with EPAR technology. This would geographically expand radio over fiber connections via wide area dispersed access over radio over fiber, providing a multi antenna-like single active RF-chain characteristic[6].

Mobile Cloud Networking Project provides on-demand cloud-based mobile elastic networks. The emphasis is on developing package systems and on the management of their lifecycles.

Mobile networking is intended to solve Fifth Generation problems with the development of new technologies for the offloading of terminals via the use of a range of download methods, e.g. WiFi cellular connections. Offloading IP traffic controlled by the network is also mentioned.

European Cooperation in Science and Technology activity on Cooperative Radio Communications for Green Smart Environments, scientific scope of radio communication systems and networks and intelligent environments is energy efficient, as the name suggests.

Network of Excellence in Wireless Communications emphasis of the project is on interdisciplinary and long-term research. The ultimate limits of communications networks, energy and spectrum efficient communications and networking, as well as opportunity and cooperative communications, are examples of research goals. It also promotes academic-industrial co-operation and training of new researchers, for example, by organizing summer courses.

Software-Defined Access utilizing Low-Energy Subsystems project aims to create a new 10 Gbps fixed access service that provides transparent transport services for both fixed and mobile clients and a low-cost wireless access connector service. The convergent network architecture includes improved management and control plans with open access and multi-operator capabilities.

Links-on-the-fly Technology for Robust, Efficient and Smart Communication in Unpredictable Environments The project examines varied and dense future networks as a viable foundation for a loss-based network design for communication connections. RESCUE has been at the forefront of public safety and automobile applications.

Aerial Base Stations with Opportunistic Links for Unexpected & Temporary Events project focuses on future public safety communication systems. The suggested heterogeneous network design is based on the following elements:

- low altitude aerial LTE-A base stations
- portable land mobile LTE-A base stations
- advanced multimode LTE-A professional terminals

Low EMF Exposure Future Networks project has a very realistic goal of finding feasible methods to reduce public electromagnetic field exposure by at least 50 percent without compromising service quality.

LITERATURE REVIEW

J. G. Andrews et al. stated in the paper that what would Fifth Generation be? What it will not be is an incremental improvement on 4G. The past four generations of cellular technology have each been a significant paradigm change that has destroyed backward compatibility. Indeed, Fifth Generation will need to be a paradigm change that incorporates extremely high carrier frequencies with enormous bandwidths, extraordinary base station and device densities, and unprecedented numbers of antennas. However, unlike the previous four generations, it will also be highly integrative: connecting any new Fifth Generation air interface and spectrum together with LTE and WiFi to offer global high-rate coverage and a seamless user experience. To enable this, the core network will also have to achieve new levels of flexibility and intelligence, spectrum control will need to be rethought and enhanced, and energy and cost savings will become even more important concerns. This article addresses all of these issues, highlighting important difficulties for future research and preliminary Fifth Generation standardization efforts, while giving a thorough review of the existing literature, and in particular of the papers featured in this special issue[7].

I. Chih-Lin et al. stated in the paper that in the face of the exponential growth of mobile Internet, engineers across the globe are searching for wireless solutions for the next generation to meet the anticipated needs of the 2020 age. Our viewpoint on Fifth Generation technology is given in this article with two key topics, green and soft. The Shannon theorem and conventional cell-centered design may be rethought to significantly increase network capacity while decreasing network power consumption. In five linked areas of research the potential of green and soft combining is investigated: energy efficiency and spectral co-design, no more cells, replenishment / control, invisible base stations, and full duplex radio[8].F. Boccardi et al. stated in the paper that the design of future fifth (Fifth Generation) cellular networks will be modified in the wake of additional study. This study presented 5 technologies that could lead to disruptive architectural and component change: device-centered designs, millimeter wave, large MIMOs, smart devices, and machine-to-machine support. The fundamental concepts of each technology and their possible effect on Fifth Generation and the remaining research difficulties are explained[9].

N. Bhushan et al. stated in the paper that this study looks at network density as the key mechanism for the next decade for wireless growth. Network densification comprises area densification and frequency densification using greater parts of radio spectrum in different bands. The self-organizing networks and intercellular interference management enable wide-ranging cost-effective spatial densification. Full benefits of densification can only be realized if they are backed by backhaul and advanced receivers that are able to remove interferences[10].

DISCUSSION

In this part you will mainly examine the 7th FP7 Future Networks Cluster Radio Access and Spectrum Projects, which handle most of the research activities of the European 5-G Group. Horizon 2020 and Fifth Generation Public Private Infrastructure Partnerships coordinate new research initiatives and activities.

The Twenty-Twenty Information Society facilitator is the biggest Fifth Generation FP7 project (29 partners) with the goal of establishing the foundation for Fifth Generation systems and serving as a consensus builder towards standardization. It has developed several test cases and scenarios to highlight and solve the major issues Fifth Generation will encounter (see Fig. 2). The possibilities are given as:

- Amazingly quick
- Great service in a crowd
- Best experience follows you

- Super real-time and stable connections
- Ubiquitous objects communicating

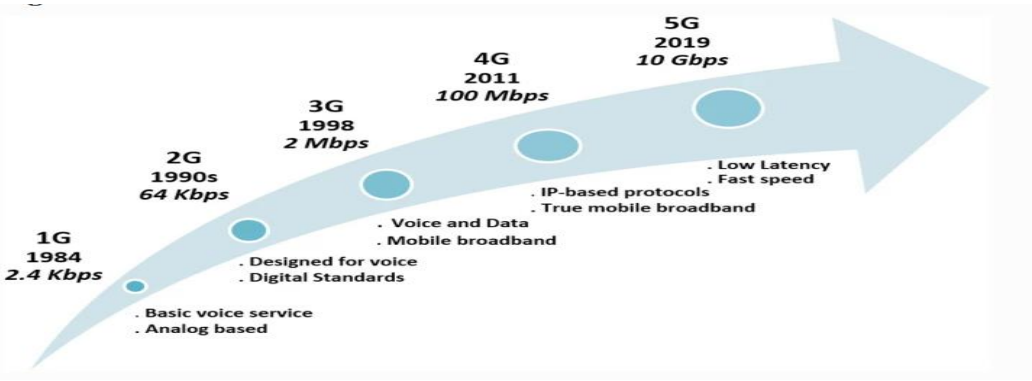

Fig. 2: Development of Service Types over Wireless Mobile Generations.

The first one is centered on the extremely high latency of data rates that is instantaneous connection. In the second scenario sufficient user experience should be provided in highly crowded venues such as shopping malls, stadiums and rock concerts. The third scenario focuses on user mobility with high service experience again, for example vehicle communications. New case/applications with high reliability and latency requirements are added in the fourth scenario. The current situation is about handling a large number of devices effectively e.g., machines, sensors.

It has also defined so-called horizontal themes to be combined with technological components to create the overall system idea. These are:

- Direct device-to-device connection
- Massive machine communication
- Moving networks
- Ultra-dense networks
- Ultra-reliable communication

Finally, an architectural framework is in place to combine various centralized and decentralized methods with a cohesive concept.

CONCLUSION

This article provides an overview of different Fifth Generation projects globally and particularly in Europe. Key publications, projects and events with a focus on Fifth Generation technology are given special attention. The research shows growing common components yet the Fifth Generation concept stays intact. Performance gains are mainly expected by combining network density, an increase in spectrum and better wireless communications technologies, increased carrier aggregations, and spectrum sharing beyond 6 GHz frequencies. The proportion of network connections and traffic will grow in the type of computers for communication. The combination of mobility and highly reliable communications really calls for novel solutions under difficult propagation conditions due of tight technological limitations. Network Virtualization will also play a significant role for Fifth Generation, in especially in the form of Cloud RAN development. Cases, scenarios, and allocations for spectrums are all so varied that the integration of the whole Fifth Generation system concept needs the greatest agility, scalability, and re-configurability.

ABSTRACT

More inventive and imaginative concepts are required as a result of advancements in wireless technology and the automation sectors. This has aided in the monitoring and control of equipment from afar. A wireless system for home automation has been proposed as part of a system that monitors and controls devices and loads remotely. The proposed plan is cost-effective. With the aid of such automated systems, a network has been created that connects peripheral equipment, smart chip bearing appliances, and many other subsystems. As a result, real-time remote control of power operation is possible. To guide the devices according to the demand and need, these systems will require radio link connection or wired communication. Radio link communication, like cable communication, has certain drawbacks, such as range restrictions, reduced data rates, greater costs, software configuration, and wire deployment.

KEYWORDS:*Mobile, Control, Automation, Global System for mobile communication, Wireless Network, Interactive Voice Response System, Short Messaging Service.*

1. INTRODUCTION

Bangladesh's AC power supply, provided by the Power Development Board (PDB), varies from time to time. Furthermore, in rural regions, supply voltage is often lower than stated. This presents a significant danger to high-tech electrical gadgets. As a result, numerous critical electric machines or equipment may be destroyed. Power quality issues, such as voltage sags, surges, and brownouts, have a significant detrimental effect on industrial output[1]. This seems to be true for both developed and developing countries. As a result, maintaining an acceptable pre-specified input voltage has become a requirement in both rural and urban regions. We'll need to utilize the Automatic Voltage Regulator to preserve them. An AVR is an electrical device that controls the fluctuation of input voltage to a load at a predetermined level. The voltage of the main power supply may be influenced by a variety of troublesome physical variables, necessitating the use of specific regulating equipment to maintain the voltage stable. Programmable AVR is a better alternative to AVR since it is more versatile, easier to change, and has the best accuracy and hysteresis.

Wireless technology is a crucial and determining element for effective operation in the automation sector. With the advancement of technology and the advent of network-based automation systems, it is now feasible to remotely monitor and operate equipment. Various technologies such as Bluetooth, DTMF, and ZigBee may be utilized to do this. These automated systems have grown quickly and have a large potential for expansion, and they will aid in the appropriate organization of gadgets and appliances for ease of use. With the aid of such automated systems, a network has been created that connects peripheral equipment, smart chip bearing appliances, and many other subsystems.As a result, real-time remote control of power operation is possible. To guide the devices according to the demand and need, these systems will require radio link connection or wired communication. Radio link communication, like cable communication, has certain drawbacks, such as range restrictions, reduced data rates, greater costs, software configuration, and wire deployment. As a result, a GSM-based system with IVRS integration has allowed users to manage and monitor appliances and loads remotely. GSM-based home automation systems have been created and deployed, using GSM-based cellular networks that have previously been established and implemented.

The GSM-based mobile phone may be utilized as a commanding device, eliminating the need for a transceiver. As a result, apart from the user instructions, no further equipment is required. The GSM network uses radio waves to communicate and is capable of sending information in real time for remote monitoring and control of devices. For simplicity of use, the IVRS allows the user to interact. Because mobile networks have bigger networks and greater coverage than local area networks, it is simpler for users to arrange the system using portable phones. The different components of the proposed system are shown in figure 1 as a block diagram[2]. A set of instructions to switch on and off the necessary devices is already programmed into the microcontroller. A symbol or a combination of symbols has already been assigned to a command in the keypad. To operate any device, a call must be made to the consumer's SIM number, after which the interactive voice response system will send the user a pre-recorded voice. Consider the following scenario: To turn on the load, press 1, and to turn it off, press 2. The user will choose an option using the control unit based on the need, which will then be transmitted to the appliance control unit through the worldwide system for mobile communication. All of these instructions are encoded in dual tone multiple frequency before being transmitted to a frequency decoder [3]. The MCU's role here is to carry out these instructions before passing them on to the relay's circuitry, which will carry out the required action. Thus, by completing all of these procedures, the gadget or appliance will be switched on or off, and the user will receive appropriate messages through GSM technology. The units in the block diagram are described in depth, such as the GSM module:

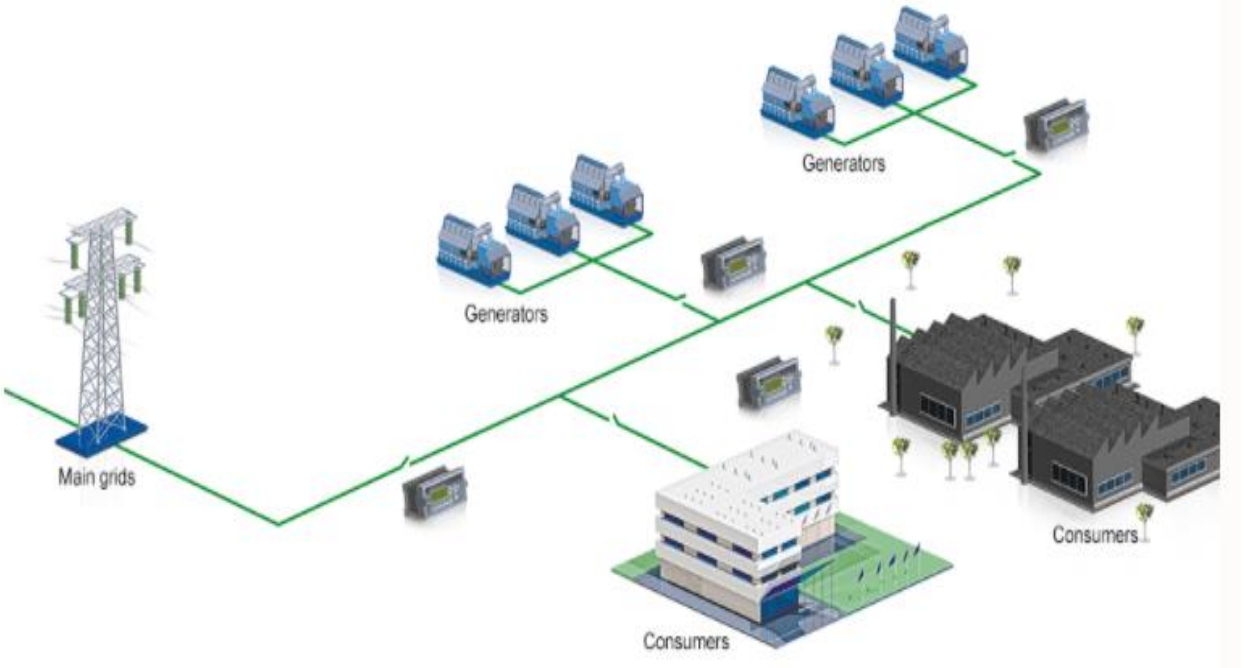

Fig. 1: Diagram Used to Show Wirelessly Load Sharing

The delay generated throughout in the execution of a command involving single control is given. The equation for calculating the complete latency of the system implemented is given[4].

While the nature of the high complexity and nonlinearity of power systems varies, power control system engineers confront difficulties together. In order to achieve excellent quality, modern generator controllers have been established in a variety of studies and have been published in many publications. Traditionally, linear control theory is used to construct excitation controllers.

AVR is the most common conventional excitation controller. Power AVR systems have been created in a number of forms to reflect the many kinds of utilized. Automatic voltage regulators (AVRs) are not conventional, and they are utilized on a wide scale with a modern design and linear transfer machine operations. However, all of the components of a modern generator, such as the governor and exciter systems, are nonlinear. As a result, a control system is only valid for a limited number of periods. The AVR system is unable to react adequately throughout the full spectrum of working circumstances due to its linearized model-based design, Benefits, and good outcomes. Negative results from a linearized AVR model are possible

Damping has a negative impact on the situation's stability. Many research have been conducted to create a quicker and more accurate reaction to work circumstances that may lead to uncertainties, as well as adaptive self-tuning of AVRs to act as a controller as shown in the Figure 2.Negative results from a linearized AVR model are possible. Damping has a negative impact on the situation's stability. Negative results from a linearized AVR model are possible. Damping has a negative impact on the situation's stability. As a result, in order to have a quick controller, numerous studies and responses to work circumstances may lead to more precise and adaptable uncertainties own.

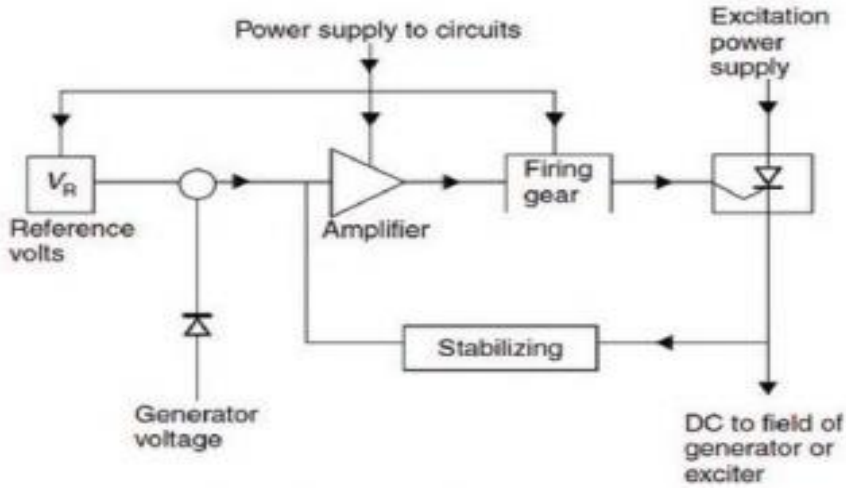

Figure 2: AVR to Act as a Controller

The AVR's primary function is to ensure that the distribution system is sufficient during voltage constant monitoring, there is a lot of reactive power. Improvements to the parallel work machine's stability. Upanna A machine's speed excitation system assists in maintaining the voltage control reactive power flow and the rate of the machine. Terminal. Increases the terminal voltage of a machine's speed.On the contrary, as R upanna points out, reactive power consumption is increasing. A sensor detects the change in terminal voltage. Transformer's potential (PT). Fix by utilizing an AC output with a set voltage. A Dc is used to connect the sensor and the proper product separator. Signal strength as a reference a device for controlling excitation to reestablish the voltage signal and the main course in an upanna. The exciter is the lack of a nominal terminal.

The GSM sim300 module is utilized, and it may be used for SMS alerts, remote control, and sensor monitoring, among other things. The model communicates with the controlling unit through an RS232 interface. This device has two functions. The first step is to create a suitable connection between the user and the ACU through the network's radio link. Another option is to provide information about the device's ON or OFF state. When the GSM module receives a call, the system's purpose is to check the user's password authentication, and only the authorized user is connected through GSM. The user will next get the necessary voice messages, which will include the set of instructions that he or she must follow through the GSM network. The commands chosen by the user are then transferred to the DTMF decoder, which performs a control action based on the instructions provided by the user [2].

If a change to the parameter is needed, the main control unit will be stopped to update the status of the user's change. If the change is made over the phone, the data is sent through the RS232 interface. Because the GSM module does not save any commands, each command is regarded as urgent and action is performed immediately. Transmitting and receiving module: If there are several ACUs, a transceiver module is used to send and receive data between them, assisting in the execution and termination of existing orders. A CC1000 UART module, which is an ultra-high frequency transceiver for lower voltages and lower power, is utilized for this purpose. The DEIF power management solutions include the ALC Automatic Load Controller. It may be essential to manage the system load if the generator is driven while the mains grid is unavailable. When the ALC is installed in a system section, it will be able to regulate up to eight consumer feeder breakers [5].

One system can hold up to 8 ALC units, giving the possibility to control up to 64 feeder breakers. For each feeder breaker, the control can be based on a fixed power consumption value for the consumers connected to the feeder, or it can be based on a power measurement feeding a

4-20 mA signal into the ALC units[6].The ALCs may automatically connect and disconnect customers in a predetermined sequence based on the power calculation in the system. This implies that if a generator is tripped for whatever reason, the system will calculate the power flow and disconnect the required number of consumer feeds to avoid the plant from being overloaded. If a generator is removed and then reinstalled, the system will determine if the generator is required to supply the system. If this is the case, the generator will be started, and the consumer feeds will be connected once it is online [7].

LITERATURE REVIEW

The authors AfshanMulla, JaypalBaviskary, JeetDesaiz, ChandrashekharBeralx, and AnaghaJadhav developed a system that combined GSM and IVRS technologies for the aim of remotely monitoring and managing equipment. A GSM-based system eliminates the requirement for a transceiver [1]. The authors, Carelin Felix and I. Jacob Raglend, reviewed the current home automation system as well as the barriers to adoption of these technologies. Furthermore, using Zigbeetechnology, a new architecture has been suggested and executed. Authors Seong Phil Hong, JaypalBaviskar, AfshanMulla, AmolBaviskar, and Jeet Desai have developed how it uses a DTMF-based system to read the remote control of different devices and supports parallel connections. By integrating the DTMF concept, a secure method for managing loads and devices has been provided [8]. Mohammad MurshadulHoqu studies the development and implementation of a Programmable Automatic Voltage Regulator (PAVR) with improved accuracy, hysteresis, and anomaly protection. Locally available systems are imprecise and suffer from oscillation between two output voltages, resulting in a surge at the output that may destroy expensive equipment. While the load varies, power voltage stability, output wave rate reduction, and unchanging power-voltage to the instruments are required to prevent these. This necessitates the maintenance of a steady voltage as well as quick response to changes in input voltage and load. This paper defines the flaws and introduces a new system in the tolerable to control the entire system automatically using a microcontroller and some protection devices to detect faults, and the circuit implementation in this system is simpler and more flexible than traditional analog control circuitry. To improve performance, a simulation of both the circuit and the software was completed[9].

PriyankaMadanraoPatil studies for today's world, a power system is essential. DISCUSSION

This paper discusses about the Wireless technology is a critical and deciding factor in the automation industry's success. It is now possible to remotely monitor and control equipment thanks to technological advancements and the introduction of network-based automation systems. This may be accomplished using a variety of technologies such as Bluetooth, DTMF,

and ZigBee. These automated systems have rapidly developed and have a lot of room for growth, and they will help with the proper arrangement of devices and appliances for convenience of use. A network has been established with the help of such automated systems, which links peripheral equipment, smart chip bearing appliances, and a variety of other subsystems**.**The microcontroller has already been configured with instructions for turning on and off the required devices. In the keypad, a symbol or a combination of symbols has already been allocated to a command. A call to the consumer's SIM number is required to operate any gadget, after which the interactive voice response system will send the user a pre-recorded voice. Consider the situation below: Press 1 to turn on the load, and 2 to turn it off. The user will utilize the control unit to choose an option depending on their needs, which will then be sent to the appliance control unit through the global mobile communication system. Before being sent to a frequency decoder, all of these instructions are encoded in dual tone multiple frequency**.**

Based on the system's power calculation, the ALCs may automatically connect and disconnect consumers in a predefined order. This means that if a generator is tripped for whatever reason, the system will calculate the power flow and disconnect the necessary number of consumer feeds to prevent overloading the plant. The system will detect whether a generator is needed to feed the system if it is removed and then reinstalled. If this is the case, the generator will be started, and after it is operational, the consumer feeds will be linked.Damping has a detrimental effect on the stability of the situation. Many studies have been carried out to develop a faster and more accurate response to work situations that may cause uncertainty, as well as adaptive self-tuning of AVRs to serve as a controller.A linearized AVR model may provide negative outcomes. Damping has a detrimental effect on the stability of the situation. Many studies have been carried out to develop a faster and more accurate response to work situations that may cause uncertainty, as well as adaptive self-tuning of AVRs to serve as a controller. A linearized AVR model may provide negative outcomes. Damping has a detrimental effect on the stability of the situation. As a consequence, many research and reactions to work conditions may lead to more precise and adaptive uncertainties own in order to have a fast controller.

CONCLUSION

The suggested system makes use of cutting-edge technology to assist users in managing and operating different appliances and gadgets in real time and from a distance. It may be seen as a significant answer to issues that emerge when the person or owner of the home is far away and unable to monitor or manage the gadgets and appliances in real time. In this article, a suitable design and implementation of a home automation system based on GSM technology is presented. The use of developing technologies such as Interactive voice response systems, in which the user may give instructions through voice messages, has been suggested and explored. Also computed and analyzed is the delay produced in the system as a result of execution and operation. The work that can be done in the future is to create new technologies and equipment that can decrease the latency generated in the entire operation. As a result, the IVRS system assists the user in remotely monitoring and managing loads and devices. A total of n bits are taken into account while putting down the equations. The total delay caused by all GSM calls adds up to an average of four seconds. The propagation latency varies depending on the distance between users, cell size, and BTS. The propagation delay is approximately 0.1milisecond for a cell size of thirty kilometers. Due to processing time, an additional 0.3-0.6 millisecond delay is imposed. Because the incoming signal is transmitted to all users, there is a rest delay. The user will also take their time entering their login and password, causing considerable delay. It will take some time to execute instructions and programs delivered to the memory. As a result, the initial control action has a delay of approximately 6-10 seconds.

THE ROLE AND IMPORTANCE OF PHYSICAL TRAINING AND SPORTS EXERCISES IN THE HEALTH OF A DEVELOPED GENERATION

Boratov Odiljon Muxammadjonovich*; Erkaev Eldor Abdukarimovich**

*Department of Physical Culture and Sports,
Fergana Polytechnic Institute,
Fergana, UZBEKISTAN

ABSTRACT

In this article, the culture of the state and society in the field of sports is to accelerate the development of physical and mental health of these segments of the population, which is of paramount importance to increase physical activity, physical culture and sports. forms vitality is shown to form feelings of patriotism and patriotism.

KEYWORDS: *Physical Education And Sports, Health Promotion, Physical Education, Physical Culture, Training, Physical Education Classes.*

INTRODUCTION

Extensive work has been done to develop a sense of patriotism, the selection of talented athletes and the systematic organization of targeted training.During the years of independence, our country has created modern conditions for the population, especially the younger generation, to regularly engage in physical culture and mass sports.

Through sports competitions, young people are developing confidence in their will, strength and abilities, courage and patriotism, famous athletes who are raising the flag of our Motherland.Most importantly, these competitions have become a means of introducing our youth to sports and a healthy lifestyle [1-4].

At the same time, today the coverage of all segments of the population with physical culture and mass sports, the active promotion of physical culture and mass sports in all regions of the country is one of the main conditions for physical and mental health and maturity. Issues such as training, creating the necessary conditions for young people to realize their abilities and talents, the selection of special talents in the field of sports and improving the system of targeted training are waiting for a systematic solution [5-11].

The material and technical base of several sports facilities does not meet modern requirements, the level of effective use of sports facilities remains low. Active movement, especially physical activity, is one of the most important factors in the development and formation of a person.It is known from the experience and observations of several scientists that optimal movement allows children to develop physically and increase their abilities.If physical activity is excessive, the

benefits of exercise are reduced and the body is negatively affected, while excessive mobility has a severe effect on young exercisers.

THE MAIN PART

The next generation is the wealth of the state. If the family is healthy and strong, there will be peace and harmony in the community. Therefore, peace and stability will prevail in the country only if the community is strong. After all, family well-being is the basis of national well-being. For many years, mankind has taken a creative and practical approach to the issue of the healthy upbringing of the younger generation

Emphasizing that physical education and sports are an integral part of the process of strengthening health, as well as the harmonious development of the younger generation, they highlighted the role of physical education and sports in educating a harmoniously developed generation. Research on the development of a healthy generation shows that the impact of physical education and sports on the formation of the child's body is invaluable. The human body regularly experiences a biological need for action [12-19].

The introduction of the position of "Athlete" in the staff of the Republican schools of higher sports and children and youth sports is an important step towards further strengthening the system of financial support for members of the national teams of Uzbekistan. The program also includes children's and youth sports specializing in sports in order to systematically organize and manage the activities of after-school sports clubs and sports clubs for schoolchildren and students in sports facilities of all educational institutions. It is planned to introduce the position of "Sports Club and Selection Coach" in schools and children's and youth sports schools. With the introduction of this position, in addition to sports clubs organized in educational institutions, thousands of pupils and students will be covered and opportunities will be created for them to go in for sports on a regular basis. In addition, the program provides for the introduction of a rating system for the activities of educational institutions and sports clubs specializing in physical culture and sports in the Olympic, national and other sports. The establishment of the badge "Excellence in Physical Culture and Sports" will serve to further encourage the work of volunteers in the field. According to the program, the three-stage program of sports games "Umid Nihollari", "Barkamol Avlod" and the Universiade will be held among schoolchildren and students. radical improvement of the system of appropriate incentives. Transparency in the selection and admission of talented athletes from among young people, the organization of the Republican and regional councils for the systematic organization and control of their targeted training, the selection and admission of talented athletes to educational institutions and sports clubs specializing in physical culture and sports and there is no doubt that the implementation of measures to ensure objectivity will ultimately serve to increase the share of achievements of our athletes in international competitions [20-23]. By further strengthening the role of physical culture and mass sports in the life of our society, the formation of a healthy lifestyle among all segments of the population, creating all conditions for young people to realize their abilities and talents. Familiarity with the way of life, as well as the expansion of the ranks of our famous athletes, who raise the flag of our country in prestigious international arenas. These actions serve as an active biological stimulus to physical maturity and intellectual development. The period of intensive growth and development of the organism coincides with the period of childhood and adolescence. Observing the passive state of the growth process in the child's body leads to the fact that during adolescence, there are signs of disease in the musculoskeletal system and internal organs. The child develops mental discomfort. Today, there is scientifically based research on the significant impact of physical education and sports on the formation of a healthy and harmoniously developed citizen of the republic, the ability of children to withstand the adverse effects of health and the external environment.

Physical education and sports stimulate the mental and spiritual well-being of children and adolescents, as well as instil feelings of patriotism and love for the Motherland.

Physical education and sports can give a lot to a child and a teenager.

It can occur as a result of physical development, physical qualities and movement skills, improvement of skills, increase of body resources and working capacity, strengthening of immunity against many diseases.

If a child's physical and motor skills are developed from an early age, they will be more effective as they grow older.

It is known that physical qualities are formed in a person from birth.

But the extent to which a child develops these qualities, whether he or she learns simple or complex movements, depends not only on the environment in which he or she lives but also on how the child develops certain physical skills.

Proper use of exercise, monitoring how children learn, allows them to develop the physical qualities of these children, their posture, the development of physical and motor skills in the right direction.

Studies by experts have shown that during the early school years, a child's physical skills and life movement skills develop more effectively through national and action games. Also, depending on the type, direction and purpose of physical activity (occupation, household, sports, military activity, etc.), the role of each physical activity in the performance of this movement will be different.

However, the integral development of these physical qualities is important in sports.

But often, in the course of all actions, the predominance of certain physical qualities is immediately apparent. The leading tasks of physical education in primary education include:

The tasks of physical education of this young generation include:

-Promoting health, strengthening students, promoting their proper physical development and maintaining high mental performance;

-Training of physical qualities (flexibility, strength, speed, agility, and endurance) and the formation of vital movement skills and abilities: walking, running, jumping, throwing, overcoming obstacles, line training;

-Equipping students with specialized knowledge and skills in the field of physical education and sports.

CONCLUSION

In summary, in the process of physical education and sports, students develop willpower qualities such as aspiration, initiative, perseverance, courage, discipline, as well as mutual friendship and appreciation of teamwork, which are necessary for them. feelings like homeland protection are formed.

TWO-POINT SECOND BOUNDARY VALUE PROBLEM FOR A QUADRATIC SIMPLE SECOND-ORDER DIFFERENTIAL EQUATION SOLVED BY THE BERNOULLI EQUATION

M.Y.Qosimova*

*Senior Lecturer,
Department of Higher Mathematics,
Fergana Polytechnic Institute,
Fergana, UZBEKISTAN

ABSTRACT

This article examines the uniqueness of the solution of the boundary problem for the second regular ordinary differential equation, which is solved in the Bernoulli equation. The uniqueness of the issue is proved by the principle of extremes.

KEYWORDS: *Bernoulli Equation, Unity of a Solution, Ordinary Differential Equation, Availability of a Solution.*

INTRODUCTION

Problem Statement

$$y'' + P_1(x)y' + P_2(x)y'^2 + P_3(x)y'^3 + P_4(x)y'^4 = P(x), \qquad x \in [x_0; x_1] \qquad (1)$$

equation and

$$y'(x_0) = y_0,\ y(x_1) = y_1 \qquad (2)$$

Find the function $y(x)$ that satisfies the boundary conditions. Here $P(x), P_1(x), P_2(x), P_3(x), P_4(x)$- given continuous functions.

Theorem. $p_1(x)-$ (1) is a special solution of equation (2) that does not satisfy the boundary condition, $P_3(x) + 4P_4(x)p_1(x) = 0$, $P_2(x) + 3P_3(x)p_1(x) + 6P_4(x)p_1^2(x) = 0$ and $P_1(x) + 2P_2(x)p_1(x) + 3P_3(x)p_1^2(x) + 4P_4(x)p_1^3(x) = Q_1(x)$,

$\int_{x_0}^{x_1} p(x)dx - \int_{x_0}^{x_1} p_1(x)dx \neq 0$ $Q_1(x) \neq 0$, $x_1 - x_0 \leq 1$,

$p_1' + P_1(x)p_1 + P_2(x){p_1}^2 + P_3(x){p_1}^3 + P_4(x){p_1}^4 = P(x)$

if the conditions are satisfied, then the problem S_1 has a unique solution.

ProofUsing the notation $y' = p(x)$ in Equation (1), we construct the following equation

$p'(x) + P_1(x)p(x) + P_2(x)p^2(x) + P_3(x)p^3(x) + P_4(x)p^4(x) = P(x)$ (3)

And condition $\int_{x_0}^{x_1} p(x)dx = y_1 - y_0$ (4) from the boundary conditions (2);

The resulting {(3), (4)} is in the new case

$$p(x) = p_1(x) + z(x), \quad (5)$$

By performing the substitution and after some elementary simplification we form the

$$z'(x) + \left(P_1(x) + 2P_2(x)p_1(x) + 3P_3(x)p_1^2(x) + 4P_4(x)p_1^3(x)\right)\cdot z +$$

$$\left(P_2(x) + 3P_3(x)p_1(x) + 6P_4(x)p_1^2(x)\right)\cdot z^2 + \left(P_3(x) + 4P_4(x)p_1(x)\right)z^3(x) +$$

$$+P_4(x)z^4(x) = P(x) - \left[p_1'(x) + P_1(x)p_1(x) + P_2(x)p_1^2(x) + P_3(x)p_1^3(x) + P_4(x)p_1^4(x)\right]$$

Equation. If we apply the conditions of the theorem to this equation

$$z'(x) + Q_1(x)z(x) = -P_4(x)z^4(x) \quad (6)$$

Based on the substitution of Bernoulli's equation and (4) from the boundary condition (5)

$$\int_{x_0}^{x_1} z(x)dx = \int_{x_0}^{x_1} p(x)dx - \int_{x_0}^{x_1} p_1(x)dx \quad (7)$$

we create the condition. (6) in equation

$$t(x) = 1/z^3(x) \quad (8)$$

by carrying out a replacement,

$$t'(x) - 3Q_1(x)t(x) = 3P_3(x) \quad (9)$$

while the equation and (7) condition

$$\int_{x_0}^{x_1} t(x)dx = \frac{1}{\left(\int_{x_0}^{x_1} p(x)dx - \int_{x_0}^{x_1} p_1(x)dx\right)^3} \quad (10)$$

we form the condition. As a result, we come to the new {(9), (10)} issue.

Let's assume, {(9'),(10')} issues $t(x) \not\equiv 0$, $x \in (x_0, x_1)$ to have solutions. Without it $\sup_{[x_0,x_1]} |t(x)| = M > 0$ here $x \in [x_0, x_1]$.

At first, we assume that $x \in (x_0, x_1)$. If this is the case, the $t(x)$ function x at the point to the value extremum will be able. Without it the $t(x)$ function'sfirst orderly to the surge $t'(x) = 0$. We have them given the fact and terms teorema,

$$\left[t'(x) - 3Q_1(x)t(x) \right] \geq 0 \ (< 0)$$

you will be able disparities. This while (9') is contrary to equality. It means that $x \in (x_0, x_1)$.

You $x = x_0$ say, $\forall x \in (x_0, x_1]$ for the $|t(x)| < |t(x_0)| = M$ disparity is appropriate. It (10') equal

$$M = |t(x_0)| = \left| \int_{x_0}^{x_1} t(x)dx \right| \leq \int_{x_0}^{x_1} |t(x)|dx < M(x_1 - x_0)$$

that $M < M(x_1 - x_0)$ the disparity stems from wrong see confirmation. It means that $x \neq x_0$ .The same (as 10') show, using equal you know, you can $x \neq x_1$ .Obtained from the above contradiction $x \in [x_0, x_1]$ to conclusions that come out. Veyershtrass this is contrary to teorema.

Therefore, $t(x) \neq 0$, $x \in [x_0, x_1]$ we assume that all is wrong. Then $t(x) = 0$, ie $t_1(x) = t_2(x)$, $x \in [x_0, x_1]$ stems from the fact that. The theorem is fully proved.

ABSTRACT

Deep learning (DL) is a cutting-edge image processing and big data analysis method with enormous promise. Deep learning is a relatively new technique in the agricultural sector, but it has already shown to be effective in other fields. This article examines how various deep learning methods have been used to numerous agricultural issues, including disease detection and identification, fruit/plant categorization, and fruit counting, among other things. The article examines the models used, the data source, the results of each research, the hardware used, and the potential of real-time application to investigate future integration with autonomous robotic platforms. The findings show that deep learning produces high-accuracy results that, with a few exceptions, outperform conventional image processing methods in terms of precision.

KEYWORDS:*Deep learning, Agriculture Data, Network Applications, Neural Network, Accuracy.*

INTRODUCTION

Agriculture is a vital component of the global economy. This industry has undergone many transformations throughout the years in order to meet the needs of the world's increasing population, which has doubled in the past 50 years. There are many projections for continued global population growth, with the world's population projected to reach 9 billion people in 2050, a 60% increase. Furthermore, the projections show a rise in the number of people living in cities and a reduction in the ratio of working to retired persons[1]. This implies that global agricultural production must rise steadily and become less reliant on human labor. Agriculture was initially exposed to technology more than a century ago, with the first tractor being launched in 1913. Mechanical technology has advanced tremendously in recent years, with a vast array of commercial technologies accessible[2]. As a consequence, production rose and human labor was reduced to a minimum. However, it may not be enough to meet global demand in the coming years. Since the 1990s, several studies have been conducted to improve production efficiency, resulting in the concept of "precision agriculture," a farm management concept based on the

observation, measurement, and actuation of crop variability with the goal of optimizing returns while conserving resources.

More recently, existing industrial technologies such as remote sensing, Internet of Things (IoT), and robotics platforms have been adapted to agriculture, resulting in the idea of "smart farming" To meet the difficulties of agricultural production in terms of productivity, environmental impact, food security, and sustainability, smart farming is critical. To solve these issues, it is essential to study and comprehend agricultural ecosystems, which necessitates continuous monitoring of many factors. For certain processes, this results in massive quantities of data that must be stored and analyzed in real time[3]. Images may be used to create this data, which can then be analyzed using various image analysis methods to identify plants, diseases, and other objects in various agricultural settings[2]. Machine learning methods such as K-means, support vector machines (SVM), and artificial neural networks (ANN) are used in certain image processing approaches. Deep learning (DL) is a cutting-edge method that has been effectively used in a variety of fields. DL is a machine learning method that is comparable to ANN but has a greater learning capacity and therefore a higher classification accuracy. To speed up the processing time of complicated DL models, various methods using specialized hardware such as Field-programmable Gate Array (FPGA) or Graphics Processing Unit (GPU) have been employed. Several DL approaches have been applied to various agricultural practices in recent years, and they have gained in favor. A review of DL applications in agriculture is presented Some DL methods are also included in other larger review publications. These studies, on the other hand, do not examine factors like as time or hardware constraints imposed by the complexity of deep learning models. With the exponential development of this field, a large number of fresh research papers using DL to agriculture can be found in the literature. As a result, the emphasis of this article is on a review of current applications of DL methods to various agricultural domains, taking into account the hardware used to execute the program. To the best of our knowledge, other review papers do not cover the works described in this article.

The approach for this review study is presented. A short description of the Deep Learning concept. All relevant work using deep learning applied to agriculture is presented and evaluated in section four. The work's findings are. This evaluation is based on two major steps: searching for recent relevant work (within the last four years); and reviewing and analyzing the gathered material. The relevant work was gathered between April and May of this year, mostly using Google Scholar as a scientific search engine. The search was open to any deep learning technique, and 29 articles from 14 different agricultural fields were chosen. The analysis of related work aims to address the following questions: I problem identification; ii) type of data used; iii) deep learning architecture; iv) deep learning model; v) overall accuracy; vi) comparison to alternative machine learning techniques and similar works in the literature; vii) used hardware and real-time application The majority of works show the Top-1 and Top-5 accuracy; however we just show the Top-1 accuracy. Top-1 accuracy is the standard: the model response must match the anticipated answer precisely. Any of the model's five highest likelihood responses must match the anticipated result, according to top-5 accuracy. Some studies use the F1 score as a quality measure, which is sufficient for binary classification tasks. Typically, writers include a thorough explanation of their quality measures; for example, provide an explanation of the F1 score metric.Machine learning techniques based on artificial neural networks include deep learning (DL) (ANN). Deep learning has a wide range of applications, including natural language processing and image processing.

Deep Neural Networks (DNN), Deep Belief Networks (DBN), Recurrent Neural Networks (RNN), recursive neural networks, Fully Convolutional Networks (FCN), and Convolutional Neural Networks (CNN) are examples of deep learning architectures that have been successfully applied to a variety of research areas, including agriculture. DL adds to the complexity of ANN

by representing data in a hierarchical manner, using several levels of abstraction. Lower levels, for example, can recognize borders in images, whereas higher levels may distinguish things like as objects or faces. Researchers may create their own model using a variety of frameworks, topologies, and data sets that are publically accessible. CAFFE, Tensor Flow, Thea no, and the DL Matlab toolbox are among of the most popular frameworks for DL experimentation, and they are utilized in several of the papers evaluated in this article. Alex Net, VGG, CaffeNet, GoogleNet, and ResNet are prominent deep learning models that are freely accessible for study. They have the benefit of being pre-trained using open data sets, which means the network is ready to detect many characteristics. These designs all use the Image-Net3 or COCO4 data sets. The major drawback of DL may be the lengthy training period and need for strong parallel programming hardware (GPU, FPGA), while traditional techniques such as Support Vector Machine (SVM) or Scale-invariant feature transform (SIFT) offer easier training procedures. However, DL techniques have a shorter testing period and are usually more accurate. The following subsections provide a quick overview of the main architectures identified in this literature review: CNN, FCN, and RNN.

1.1 Application of deep learning in agriculture

In a total of 43 recent publications, 14 different areas of DL applications in agriculture have been discovered. Only 29 articles were chosen for this evaluation, however the list of the other papers is accessible to the public 5. Disease identification (6 papers), plant identification (4 papers), and land cover and weed identification (4 papers) are the most popular topics (3 papers each). CNNs have been utilized in 24 publications, with FCN and RNN being the only other options. This review's oldest piece was published in 2016. (one article). In 2017, 3 articles were published, 17 in 2018, and 8 in 2019. DL architectures like as CNN, FCN, RNN, Single Shot MultiBox Detector (SSD), and Bidirectional Long Short-Term Memory were utilized by the authors of the many articles that were reviewed (BLSTM). However, according to the present research, CNN has been the most often used DL architecture in recent years. O and CNN is only mentioned in two of them Some authors used a CNN/FCN or CNN/RNN combination, while others used R-CNN and/or Region Based Fully Convolutional Neural Networks (R-FCN). R-CNN, as its name implies, avoids the issue of classifying a large number of regions by classifying just a few at a time, reducing classification time. Fast R-CNN and Faster R-CNN are enhanced versions of R-CNN that are utilized in three publications to accomplish real-time object detection.R-FCN increases classification speed by decreasing the amount of labor required, and it is utilized in two publications. The majority of the writers relied on publicly accessible architectural models such as VGG, AlexNet, MatConvnet, DenseNet, and Darknet (Yolo), all of which were implemented using well-known frameworks (FW). however, it is not always apparent if the author created their own model from start or changed one of the existing models. The majority of the authors created their own data set using a variety of methods, including manually captured images, images from large public data sets like ImageNet or COCO, unmanned ground vehicles (UGV) [45], or unmanned aerial vehicles (UAV) equipped with sensors to capture the desired data. To increase the dataset and enhance the neural network's outcomes, the bulk of the writers used data augmentation. The majority of the papers compare their DL approach to other machine learning methods such as SVM, SIFT, Random Forest (RF), backpropagation (BP), Particle Swarm Optimization (PSO), Multilayer Perceptron (MLP), AdaBoost, Principal Component Analysis (PCA) plus Kernel SVM (kSVM), Random Forests Uncorrelated Plant (RFUP), Random Forests Correlated Field (RFCF), Random Forests Uncorrelated Plant (RFUP), Random Forest (RFCF). With a few outliers, when conventional techniques have the same or greater accuracy, the overall accuracy of the evaluated articles is usually excellent and exceeds other machine learning methods. Only four studies in this study worked with conventional Central Processing Units, demonstrating the hardware constraints imposed by the complexity of DL (CPU). The majority

of writers utilize high-end GPUs, while used a combination of GPU and FPGA to speed up their CNN model. Only 11 publications claim to be able to execute the test procedure in real time, despite having such powerful gear[4]. The remaining writers don't say how long their networks were tested.

This analysis concludes that DL techniques in agriculture are growing at an astronomically fast rate, with a wide range of potential applications and combinations with aerial and ground platforms such as UAVs or UGVs, as DL can be used in the process of automating these machines by collecting and processing data in order to give an order to the autonomous vehicle. The authors of this study, however, only collected data using unmanned platforms. Because of the hardware requirements, completely automating a robotic platform using deep learning may be limited. GPUs, the most common hardware platform for processing DL models, have high power requirements, which may be a constraint for a robotic platform that is usually electric and battery-powered. For distant severe agricultural terrains, running the required DL tools on a remote computer and therefore saving the battery life of unmanned platforms is not always possible. FPGAs may be a low-power option, however there is currently little study on these systems in agriculture, with just one paper identified for this review[5]. As the review demonstrates, deep learning outperforms most conventional machine learning techniques in terms of accuracy, and real-time application, which is critical for autonomous cars, is difficult to achieve without DL approaches since other methods need more testing time, for example, describe a study on AGV localization in a steep slope vineyard[4]. They utilize an SVM classifier to identify natural characteristics, which needs precise and real-time detection, which this study lacks. Real-time detection is not guaranteed even with its GPU implementation. Other DL methods, as shown in the works reviewed here, may be able to conduct a faster and more accurate detection, thereby addressing the issue of localization. To summarize, DL is on the right track to collaborating with a variety of agricultural fields, and research should continue to concentrate on low-power hardware and integration with autonomous platforms[5].

1.2 Convolutional Neural Networks:

CNNs are a kind of deep, feed-forward artificial neural network that has been used to address computer vision issues. Our is the most frequent architecture, and it appears in nearly every article in this review. CNN, unlike ANN, can learn complicated problems rather quickly owing to weight sharing and sophisticated models that allow for parallelization[6]. The various convolutions are executed at certain levels of the network, producing distinct representations of the dataset, as[4]. The pooling layers decrease the dimensionality of the input pictures, so the convolutional layers serve as feature extractors[6]. The fully connected layers serve as classifiers, using high-level characteristics to categorize incoming pictures into the appropriate category[7].

If a big enough dataset is available, CNNs improve the likelihood of accurate classifications. Data augmentation is a popular method for expanding the data set and improving CNN accuracy. The dataset may be expanded by performing a series of random transformations to the original pictures, such as rotation and translation, since CNNs are invariant to translation, size, and illumination.

1.3 Fully Convolutional Networks:

FCN is a Convolution neural architecture that generates a semantic mask as an output via down-sampling (convolution) and up-sampling (deconvolution) [4]. The input picture is often reduced in size to allow it to pass through many convolution layers, with the output being a single predicted label for the input image. FCN networks do not downscale the picture, thus the output is not a single label, allowing the output to be up-sampled and the class to be predicted pixel-by-pixel.

LITERATURE REVIEW

The increasing availability (and varying complexity and types) of Internet of Things (IoT) devices, as well as the large data volumes that such devices (potentially) generate, can have a significant impact on our lives, spurring the development of critical next-generation services and applications across a wide range of application domains (e.g. healthcare, smart grids, finance, disaster management, agriculture, transportation and water management). Deep learning, which has previously proven effective in computer vision and language modeling, is now finding use in other areas thanks to the availability of vast and varied datasets[8]. One example is the use of Deep Learning technology to enhance human health via improvements in medical diagnosis and prediction. However, moving massive data streams (a prerequisite of Deep Learning technologies for attaining high accuracy) to centralized places such as Cloud datacentre settings in a timely and reliable way is regarded as a major barrier to extending the application frontiers of such technologies. To this aim, a number of paradigms have been suggested, including Osmotic Computing, which encourages the spread of data analysis activities between Cloud and Edge computing platforms.

Deep Learning (DL) techniques like as Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Generative Adversarial Networks (GAN) have been extensively researched and used in a variety of areas, including agriculture, in recent years[9]**.** Agricultural researchers often utilize software frameworks without thoroughly investigating the concepts and processes of a method. To assist agricultural researchers in rapidly gaining a holistic view of key DL methods, this article offers a brief description of major DL algorithms, including principles, limits, implementation, training procedures, and sample codes. In this paper, research on DL applications in agriculture is summarized and analyzed, and future opportunities are discussed, with the goal of assisting agricultural researchers in better understanding DL algorithms and learning major DL techniques quickly, as well as facilitating data analysis, enhancing related agricultural research, and effectively promoting DL applications.

The fast development of new technologies, as well as the changing landscape of the online world (e.g., Internet of Things (IoT), Internet of All, cloud-based solutions), provide a once-in-a-lifetime opportunity for creating automated and robotic systems for urban farming, agriculture, and forestry[10]. Robotic systems and intelligent technologies for precision agriculture have been developed and implemented thanks to technological advancements in machine vision, global positioning systems, laser technologies, actuators, and mechatronics. We show and discuss robotic plant pathology and management applications, as well as new agricultural technology for intra-urban agriculture, in this paper. In recent years, sophisticated greenhouse management systems and technologies have progressed significantly, including IoT and WSN (Wireless Sensor Network). Agriculture has used and used machine learning, machine vision, and AI (Artificial Intelligence) for automated and robotic farming. Machine vision/learning-based intelligence systems have been created not just for planting, watering, weeding (to some degree), trimming, and harvesting, but also for detecting and identifying plant diseases.

DISCUSSION

Agriculture goods are in high demand throughout the globe as a result of population increase. As a result, more agricultural output is required. Nowadays, cutting-edge technologies such as machine learning, deep learning, IoT, and robots are being utilized to boost agricultural output, save expenses, and enhance revenue. Rain, cyclones, floods, climate fluctuations, weeds, pests, and a shortage of personnel are some of the variables that influence crop development in agriculture. As a result, farmers are increasingly turning to deep learning technologies to enhance crop management and other agricultural applications. Deep learning will have a significant impact on agriculture in the future. Agriculture provides the country's food security, which is

why it is considered the country's backbone. It is crucial to the majority of the country's foreign commerce. Agriculture provides a living for roughly 75% of people in most areas of the globe. Because of the growth in population, there is a need to enhance agricultural output, therefore we must improve the condition of agriculture. Farmers are searching for cost-effective methods to improve crop output while maximizing the use of existing resources. This helps farmers make better choices and improve yields by introducing new digital technology into the agricultural sector. We can now solve numerous difficulties and obstacles in agricultural sectors utilizing deep learning techniques.

CONCLUSION

A review of DL-based research activities in agricultural areas was provided in the current article. It looked into the agricultural field and described the problem they were trying to solve, listed technical details like the DL architecture and model, described the data source, reported the overall accuracy of each work in comparison to alternative methods, verified the used hardware, and discussed the possibility of real-time applications. The results show that DL achieved excellent precision in the majority of the evaluated works, outperforming other conventional techniques. The primary benefit of non-DL methods is that the classification process takes a short amount of time, making real-time execution simpler. The hardware limitation may be the most significant drawback, since they need mostly strong GPUs with high power consumption. In the agricultural sector, alternative reduced power demand solutions (FPGAs) are currently undergoing limited study. For appropriate real-time integration with autonomous robotic platforms (AGVs), research should concentrate on reducing the complexity and hardware requirements of current efficient DL methods.

ABSTRACT

The acceptance and use of open source tools has changed dramatically as a result of global technological progress. Because most businesses across the world deal with a significant quantity of data that has to be updated online on a regular basis, and transactions happen every second, organizing, mining, and processing this dynamic data is very difficult. A thorough examination of the different tools and algorithms accessible to data mining specialists is required for successful application of the method. This paper compares the open source data mining technologies that are accessible to experts. The parameters that influence the selection of appropriate tools, as well as the real-time difficulties, are addressed. Agents, on the other hand, have been shown to improve the performance of data mining tools. This paper offers details on an agent-based architecture for data preparation, as well as implementation details, in order to help the industry create better tools. Integration of open source data mining tools with agent simulation allows for the implementation of an effective data preparation architecture, resulting in an application with strong capabilities that can be updated with little preplanning from the application developer.

KEYWORDS: *Agent based framework, Agent simulation, Agents, Data Mining, Data Mining Tools.*

1. INTRODUCTION

Organizations may now store complicated data in many places and update it in real time thanks to recent technological advancements. Any organization's primary issue is to properly handle huge amounts of frequently updated data online. One of the limiting characteristics of the Data Stream Management System has always been its inability to query both live and archive data at the same time[1]. Data mining is a technique for analyzing and discovering new patterns in data from different sources. The data mining approach is capable of solving emergent issues such as the identification of patterns and information in ambiguous, high-frequency, organizational, or

behavioral data, as well as data produced and stored in different locations systems[2], [3]. Data mining is used to obtain current information, but it adds to the complexity of data processing, management, and mining. Weka, RapidMiner, TANAGRA, Orange, and KNIME are some of the most widely used open source data mining technologies. Handling Complicated Problems, Discovering Unknown Patterns, Skill Required in Working with the Tool, Scalability, and Data Mining Tools offer us with a user pleasant interface for data analysis. Data mining software should be able to handle big datasets, according to Cost. A client server environment is required for data mining tools, according to Computer system environment. Product track record, vendor viability, breadth of data mining techniques, compatibility with a particular computer system, ease of use, and capacity to handle huge datasets are all factors to consider when evaluating data mining technologies.

Pharmine Company's data mining specialists have compiled a study on data mining tool comparisons, which assesses different data mining programs such as KNIME, Rapid Miner, Weka, Tanagra, and Orange[4], [5]. The result chart of the Data Mining Tool Comparison produced by Pharmine study is shown in Table 1.

TABLE 1: COMPARATIVE ANALYSIS OF DATA MINING TOOLS[5]

Procedure	KNIME	RapidMiner	Weka	TANAGRA	Orange
Partitioning of dataset to training and testing sets	Have with limited partitioning abilities	Have with limited partitioning abilities	Have with limited partitioning abilities	Have with limited partitioning abilities	Have with limited partitioning abilities
Descriptor Scaling	Have the facility	Have the facility	Does not have the facility to save parameters for scaling to apply to future datasets	Does not have the facility to save parameters for scaling to apply to future datasets	Does not have the facility of scaling
Descriptor Selection	Has no wrapper methods	Have the facility	Have the facility but not the part of knowledge flow	Have wrapper methods that is valid only for logistic regression	Has no wrapper methods
Parameter optimization of machine learning/statistical methods	Does not have automatic facility	Has the facility	Does not have automatic facility	Does not have automatic facility	Does not have automatic facility
Model validation using cross-validation and/or independent validation set	Have only limited error measurement methods	Has the full facility	Have the facility but is not capable of saving the model so have to rebuild model for every future data set	It does not have the capability of validating independent validation set	Have the facility but is not capable of saving the model so have to rebuild model for every future data set

One of the most difficult aspects of data mining is dealing with noisy data[6]. The existing data mining technologies do not enable real-time modeling, which allows for the acquisition of new models or knowledge as new data is uploaded. In practice, a data miner will remodel to guarantee that fresh information is acquired. This restriction causes problems in a variety of applications, including medical, stock market, and financial. These fields are crucial for having current knowledge since they have an impact on human existence and corporate performance. A thorough examination of the different tools and methods available is required for successful data

mining deployment. However, the present information age has pushed businesses to cope with gigabytes and terabytes of database instead of megabytes of database.

Data mining techniques become less and less efficient as data sets grow in size. This is an essential aspect of a data mining tool since it encourages us to examine the tool's performance[7]. It is costly to integrate the most recent knowledge model into existing data mining technologies. Every time new data arrives, it must be cleaned and mined dynamically. Furthermore, users must choose a suitable time to conduct data mining, which is another time-consuming issue. Expert users are required to conduct trials using the available data mining tools in order to get a usable knowledge model, and this should be done in a manner that treats all data equally. The user's understanding influences the method selection. Existing data mining techniques do not allow for the addition of new data or the re-modeling of knowledge when substantial new data is introduced. To obtain the updated knowledge model, the fresh data should be mined again. As a result, the existing data mining tools are not appropriate for inexperienced users.

Agent-based systems are the best way to solve the problems mentioned above. Because of their independent, flexible, adaptable, and intelligent features, agents have become a popular computer paradigm in recent years. Intelligent agents act in a logical manner. Intelligent agents do tasks with human intellect, yet they may not act like humans. When compared to traditional mining tools, the agent engaged in mining processing performs productive tasks, recovers valuable information with less noise, and reduces processing time. Agent-based data mining techniques may include the following features:

a. Propose the data-processing methods that are most appropriate.

b. Preprocess fresh data in accordance with the user's profile.

c. Exchange mining knowledge

d. Suggestions for potential information that may be derived from data using the shared experience

e. Appropriate for inexperienced users.

1.1. Agent Based Modeling and Simulation:

One of the driving factors in the development of computer systems has been computer-based modeling and simulation of (real-life) complex systems. A simulation is defined as the simulation of the functioning of a process or a real-world system over time. A computational model is a computer program that represents a real-world system using a collection of algorithms and mathematical formulae written as code in a programming language[8].

The goal of computational models, unlike pure mathematical models, is generally not to find analytical answers to particular problems. Computational models, on the other hand, allow for the creation of experiments to evaluate the created models in various situations (with different parameter configurations)[9]. These tests are carried out with the goal of determining how the modeled systems behave given a set of assumptions. This testing enables the designer to get insight into some features of a complicated system that would be impossible to discover through mathematical analysis, or for issues for which no tractable mathematical model exists.

A system is represented in ABMS as a collection of independent creatures known as agents. Each of these agents is placed in an environment (virtual or real) from which it receives information via the use of sensors and makes choices based on its perception of the environment and its goals. These choices are then reflected in activities taken to alter the environment's condition (i.e. direct actions to the environment, communication with other agents, further reasoning).

Depending on the system it populates, an agent may act in a variety of ways. Reactivity – the capacity to respond to events in the environment; pro-activity – the ability to exhibit some behavior defined by its specific aims, taking the initiative to meet its needs; and sociability – the ability to connect with other agents and people to achieve its goals. These characteristics provide a new kind of abstraction for the representation of problem domains, allowing agent-based systems to be more versatile than traditional object-based systems.

1.2. Existing Agent Simulation Tools:

We'll talk about popular agent simulation programs like Aglets, JATLite, FTP Software Agent, and Voyager in this part.

Aglets are IBM-developed Java-based autonomous agents that offer the fundamental mobility capabilities and have a globally unique name. A trip itinerary specifies the locations to which the agent must go as well as the activities that must be taken at each site. In order for an aglet to execute on a given system, the target system must be running an aglet host application, which provides the aglet with a platform-independent execution environment. A customizable Java security manager is included in the aglet workbench. Aglets may interact via a whiteboard, which enables agents to work together and exchange information in real time. Aglet communication supports both synchronous and asynchronous message passing. Aglets are serialized or externalized using normal Java serialization. The byte code stream and state of an aglet may move over a network with the help of a network agent class loader.Aglets are IBM-developed Java-based autonomous agents that offer the fundamental mobility capabilities and have a globally unique name. A trip itinerary specifies the locations to which the agent must go as well as the activities that must be taken at each site. In order for an aglet to execute on a given system, the target system must be running an aglet host application, which provides the aglet with a platform-independent execution environment. Aglet communication supports both synchronous and asynchronous message passing. Aglets are serialized or externalized using normal Java serialization. The byte code stream and state of an aglet may move over a network with the help of a network agent class loader.

FTP Software Agent Technology is Java-based software that uses agent technology to handle heterogeneous networks over the Internet. The agents are self-contained and mobile, with the ability to travel to any machine on the network that has an Agent Responder installed. The agent's duties may vary as it travels from system to system, depending on the environment of the system it is visiting. As required, the agents may communicate with other agents or with the user. FTP agents, on the other hand, do not need human involvement since they utilize push technology to travel from system to system, react to events, and execute tasks depending on user-defined criteria. The launch of the agent is the responsibility of an Agent Manager.ObjectSpace, Inc.'s Voyager is a Java-based agent-enhanced Object Request Broker (ORB)[10]. An ORB enables the creation of objects on a distant system and the invocation of methods on those objects. Voyager adds agent capabilities to the conventional ORB. Agents of the Voyager class have mobility and autonomy, as does the base class Agent. An Agent may relocate to a new location and leave a forwarding address with a secretary so that future communications can be sent to the new site. Messages are delivered by specialized agents known as Messengers. Messages may be synchronous, one-way, or future. Future messages are asynchronous but provide a placeholder that can be used to obtain a return result at a later time. The itinerary of an agent specifies the actions that must be performed at each site. The security manager in Voyager may be used to limit the operations that an agent can do.

2. DISCUSSION

2.1. Architecture Development:

Large amounts of data are generated and kept in databases as a result of the development of online transactions, the World Wide Web, data streams, and other technologies, which is one of the reasons for data management's complexity. It may be difficult for novice users to identify the optimal method for pre-processing their data in order to conduct data mining. As a result, specialists are needed to choose the optimum pre-processing method. Neither data mining technologies nor users have adequate expertise in the data mining area to handle dynamic and complicated data at this time. When an agent-based data mining system is used, the agent chooses the method and parameters that give the best model for generating excellent decisions. Because existing data mining techniques are domain specific, this study focuses on proposing a generic architecture that can pre-process data utilizing agents from any domain. Furthermore, the suggested design is simple enough for even a beginner user to utilize.

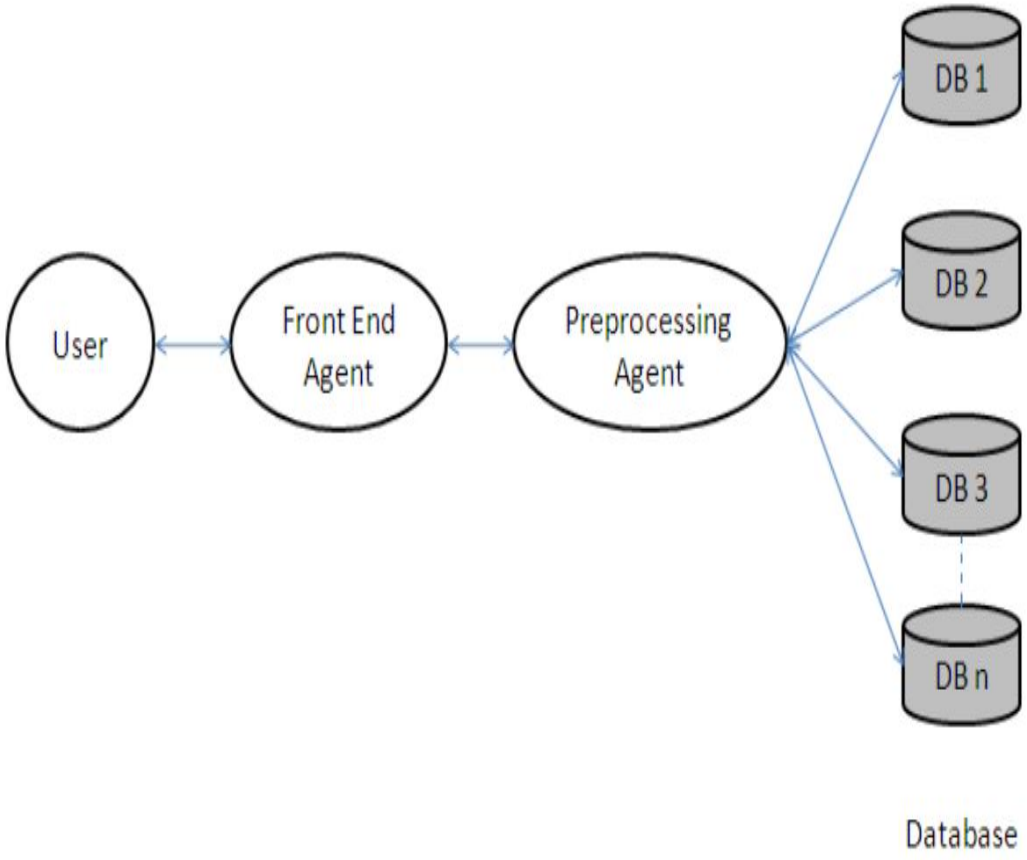

Figure 1: Illustrates the Pre-processing Architecture.

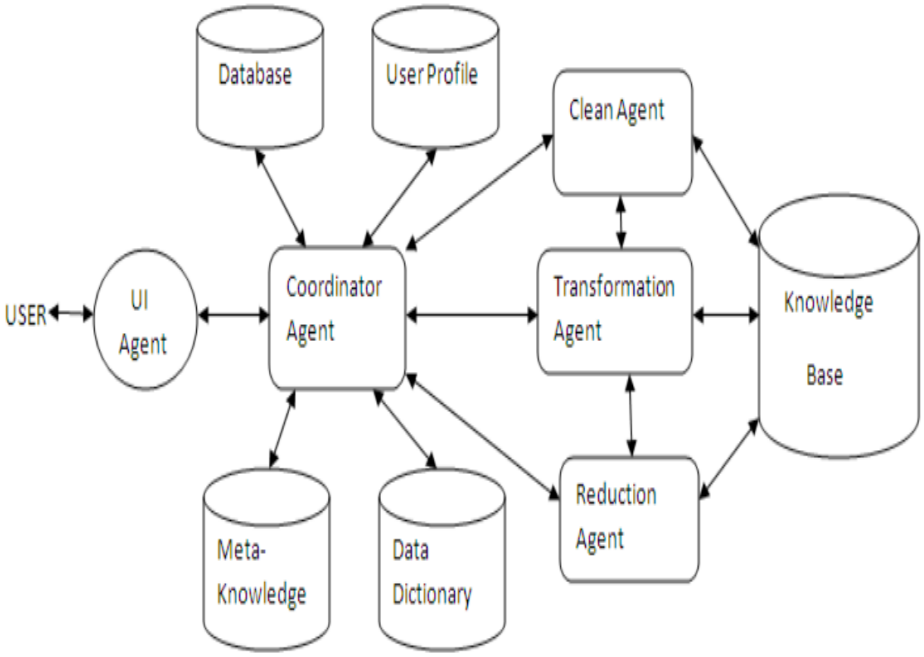

Figure 2: Illustrates the detailed Pre-processing Architecture.

The fundamental concept of Pre-processing architecture shown in Figure 1 is the suggested design. User Interface Agent (UI Agent), Coordinator Agent, Clean Agent, Transformation Agent, and Reduction Agent are the five main agents in the framework. The above-mentioned pre-processing architecture is shown in Figure 2. Each agent's duties and skills are unique. The User Interface Agent is in charge of the system's user interface. It does solution analysis on its own and assists the user in formulating questions based on their needs. The coordinator agent is in charge of coordinating all of the tasks carried out in the system. It decides the pre-processing technique to be utilized depending on the data mining job provided by the user, which is created using the agent's Meta knowledge. It has access to a dynamically updated data store and delivers data to the other agents. The coordinator agent also does adaptive profiling of user data as well as tests to identify the database's data kinds and characteristics. It detects the issues with the data and saves the information and appropriate preparation method for them. Clean Agent uses the methods in the data dictionary to deal with missing and noisy data. The Transformation Agent is used to convert the data into mining-friendly formats. The reduction agent's job is to shrink the size of the data by using discretization methods.

2.2. Implementation of the Agent Based Preprocessing Architecture:

The architectural model presented is a client-server architecture with a simple Model View Controller Architecture. The above-mentioned architecture may be implemented in a variety of ways, including creating both an agent and an application, or modifying an application's existing code to allow the required communication. All of the preprocessing techniques may be found in a variety of open source data mining and agent simulation programs.

The following are the criteria for the proposed agent framework:

a. The ability to imbue programs with intelligence.

b. An intelligent agent framework may be used to address real-world issues.

c. The architecture must be adaptable enough to accommodate a wide range of applications.

d. Intelligent agents enhance the application's functionality and may interact with one another and other apps.

e. The agents are in charge of calling the shots, as well as monitoring and controlling the applications.

2.3. Functional Specification of Agent Framework:

The following requirements are always included in Agent Framework functionality:

a. Adding an intelligent agent to an existing application should be simple.

b. To assemble agents out of other Java components and other agents, a graphical building tool must be provided.

c. The agents must be able to handle somewhat complex event processing. Events from the outside world, other agents, and signal events to external applications will all be handled by the agent.

d. Domain information may be contributed to an agent using if-then rules, and sensors and effectors can enable forward and backward rule-based processing.

e. Using learning techniques, the agents must be able to learn to perform classification, grouping, and prediction.

f. A KQML-like messaging protocol must be provided for multi-agent applications.

g. The agent must be tenacious. That is, once an agent is built, it must be possible to store its state in a file and reload it at a later time.

Because open source data mining tools and agent simulation tools are now available for the implementation of the architecture, it is now possible to append an agent to an existing application, thereby extending the application's basic capabilities with minimal pre-planning on the part of the application developer.

3. CONCLUSION

Organizations can dynamically store, analyze, and update large and complicated data thanks to technological advancements. The usage of the appropriate software tools is required for the creation and implementation of data mining methods. Furthermore, existing data mining techniques are prohibitively costly when it comes to obtaining an updated knowledge model. This paper focuses on two elements of data mining tools: elucidating a comparative analysis of different open source data mining tools and presenting the difficulties that currently exist in data mining tools. Agents, on the other hand, are known to help data mining technologies work better. As a result, in order to build an effective data preparation architecture, this paper proposes integrating current data-mining tools with agents. The functional requirements given here allow the application developer to thoroughly examine, evaluate, and build the data preparation tool for better data management.

ABSTRACT

Machine learning is a subfield of computer programming that investigates the construction of machine learning tree algorithms. Learning, predictive modelling, grouping, and finding predicted patterns are all examples of machine learning activities. These activities are learnt via the use of data that has been gathered through observations and instructions. The industries that collect large amounts of data need to be able to analyse and learn from it, and software like R allows users to visualize data, run statistical tests, and apply machine learning algorithms. R is a programming language that does not have a graphical user interface with buttons to run different methods. Data growth required the development of statistical techniques for analysing big datasets, which in turn prompted the development of computer power. Rheumatoid arthritis (RA) is an inflammatory, progressive illness that may lead to joint damage and disability if not treated properly. The existence of certain clinical and laboratory evidences may be used to predict the prognosis of RA. New RA categorization standards open up the possibility of early therapy. Treatment with a combination of DMARDs combined with a short term of corticosteroid is anticipated to prevent progression of RA and even alter the natural course of the disease. Patients with clinical synovitis in at least one joint may now have confirmed RA, which need urgent therapy.

KEYWORDS: *Machine learning, R language, gene analysis, Rheumatoid arthritis, Unsupervised learning.*

INTRODUCTION

Early in the course of rheumatoid arthritis (RA), patients rely heavily on strong pharmaceutical management of inflammation. Despite the significance of choosing the best medicine as soon as possible following the start of the illness, there is no good biomarker predictor of pharmacological treatment success. As a result, while a physician looks for an effective medication, RA patients often suffer permanent joint damage. Disease-modifying anti-rheumatic

medications are the first-line treatment for RA, whereas novel biologic therapies, such as those that block the inflammatory cytokine TNF-alpha, are extremely effective but only achieve remission in 30% of patients. The pharmacological treatment is chosen depending on the severity of the illness and the clinical prognostic characteristics[1].

A genetic biomarker linked to a high probability of biologic drug response may shift the paradigm and enhance early RA disease outcomes. The choice of treatment is based on the severity of the RA disease as evaluated during clinical visits. In RA clinical trials, the main objective is standardized disease activity levels evaluated at regular intervals. However, identifying disease activity in observational Electronic Medical Record (EMR) data before and after medication exposure is difficult because physicians seldom record disease activity in structured categories and instead describe it as free text in the clinical narrative. For example, we have a structured disease activity tool and a longitudinal cohort study at our institution that gather disease activity data at individual patient visits, however these structured data are only accessible on a small percentage of visits[2].

The Disease Activity Score in 28 Joints (DAS28) is an example of a structured tool utilized by Partners HealthCare. The instrument is assessed by study rheumatologists for RA patients who are followed yearly in a cohort study. DAS28 is a clinical trial composite indicator that has been created and validated. It is based on patient-reported global health evaluation and weighted factors for swollen joint count, painful joint count, C-reactive protein level (CRP) or erythrocyte sedimentation rate (ESR)[3]. The initial DAS algorithm was based on clinical and laboratory data collected by six rheumatologists over the course of three years in a prospective trial. Based on correlations with drug modifications, they classified disease activity as high, moderate, low, or remission. The DAS algorithm was verified in more RA patients after it was created, and it was ultimately used on thousands of patients in clinical studies, patient registries, and regular office visits. Despite the fact that the initial study was conducted in just 113 RA patients in the 1980s[4], before the advent of biological DMARDs, the algorithm's key components are still in use today.

The discovery of genetic and environmental risk factors for RA has prompted the issue of whether these risk factors are adequate to identify who is at risk of developing the illness. Indeed, predicting who may acquire illness before symptoms appear is one of the ultimate goals of genetic study. It's also worth noting that the genetic markers discovered so far account for just approximately half of the heritability of RA. Other research to account for a greater percentage of disease heredity, as well as the inclusion of additional risk variables including environmental factors, biomarkers, and clinical predictors, would almost likely enhance the prediction models' power and make them more clinically relevant[5].

Rheumatoid arthritis

The most prevalent chronic inflammatory arthritis in adults is rheumatoid arthritis, which affects between 1.3 and 1.8 million Americans. It's an illness with an unknown cause but an immunological component. RA affects more women than males and may strike at any age, with a peak incidence in the 50s and 60s. Morning stiffness and symmetrical joint swelling of the feet, hands, and knees are classic symptoms of RA, although any joint (and, in rare instances, internal organs and skin) may be affected. RA is a clinical condition that, if left untreated, may result in irreversible joint damage and deformity in certain people. Skin, eye, heart, lung, hematologic, and other extra-articular symptoms may sometimes complicate the course of RA. Patient education, psychological support and treatment, physical and occupational therapy, medicines, and, if necessary, joint surgery are all part of the RA management process[6]. The medicines utilized are classified as either treating symptoms simply or targeting tissue damage processes, which are known to as disease-modifying anti-rheumatic therapies. Methotrexate, leflunomide,

hydroxychloroquine, and sulfasalazine are examples of traditional DMARDs having wide immunomodulatory effects. More recently, a group of biologic and non-biologic medicines known as "targeted immune modulators" (TIMs) have been widely used to target mediators of inflammation in RA. In the past, RA was linked to increasing disability and a shorter lifespan, but advances in early diagnosis and active TIM usage have significantly improved survival and other important outcomes in the last 20 years[7]. The comparative clinical efficacy, possible hazards, and comparative value of the main TIMs used in the treatment of moderately-to-severely active RA despite previous traditional DMARD therapy, as well as two medicines under regulatory evaluation for this indication, are the subject of this study.

Rheumatoid Arthritis Treatments

Treatments for DMARDs may be administered alone or in combination (either with each other or more commonly, with TIMs). Inflammation is also controlled with the use of steroids.

The following are the most frequent agents:

- Methotrexate is an antimetabolite that blocks the production of folate in rapidly proliferating cells. Methotrexate at a low dosage is suggested as the first-line treatment for RA. It may also be used with a variety of TIMs to generate outcomes that are usually superior to TIM monotherapy. Methotrexate, on the other hand, is linked to a risk of hepatotoxicity, necessitates regular laboratory monitoring and folic acid supplementation, interacts with a variety of other medications, and should not be used in patients with serious liver or kidney disease, or in couples planning to conceive.
- Sulfasalazine is a sulfa medication that contains salicylate (the active component in aspirin) and the antibiotic sulfapyridine. Daily oral usage has been proven to help reduce joint inflammation in people with RA, especially in the early and milder phases of the illness. Nausea and stomach pain are common side effects, and sulfasalazine may also make you more sensitive to sunlight and cause skin discoloration.

Prediction Modelling Overview

Our analysis was carried out using the REGENT (Risk Estimation for Genetic and Environmental Traits) R package, which was created inside our unit. The literature is used to identify hereditary and environmental factors for inclusion in REGENT. In order to evaluate precision, allelic ORs, allele frequencies, and number of respondents from relevant research are needed. ORs, standard errors, and the percentage of the population exposed to the risk factor are all required for environmental risk factors. These risk variables are entered as summary statistic input files into REGENT, which are handled in two stages: the first builds the prediction model, and the second executes the prediction model using real-world data[8].

Components of Prediction Models Discovered Through Meta-Analyses

- *Factors that Increase the Risk of Cancer*

Utilizing two large, newly published meta-analyses, we discovered genetic susceptibility variations for possible inclusion in our prediction modeling. Only susceptibility alleles with genome-wide significance were included, ensuring that the alleles simulated were true RA genetic risk factors.

- *Factors Endangering the Environment*

In our simulations, we incorporated the environmental risk factor of smoking. Other factors that have been proposed to influence RA risk, such as alcohol, were not included for two reasons: first, the evidence supporting these claims is shaky, with associations frequently found in case-control studies rather than cohort studies, and second, detailed data on non-smoking risk factors was not captured in WTCCC and UKRAGG.

Aspects

Rheumatoid arthritis is thought to be caused by a mix of hereditary and environmental variables, many of which are unknown. Rheumatoid arthritis is an autoimmune illness, which is a broad term for a set of diseases in which the immune system targets the body's own tissues and organs. The immune system in individuals with rheumatoid arthritis causes aberrant inflammation in the joint membrane (the synovium). When the synovium becomes inflamed, the joint becomes painful, swollen, and stiff. In extreme instances, the inflammation spreads to the joint's bone, cartilage, and other tissues, causing more significant injury. Rheumatoid arthritis that affects other areas of the body is likewise characterized by abnormal immune responses. Variations in hundreds of genes have been investigated as rheumatoid arthritis risk factors. The immune system is thought to be implicated in the majority of these genes[9]. Variations in human leukocyte antigen (HLA) genes, particularly the HLA-DRBI gene, are the most important genetic risk factors for rheumatoid arthritis. HLA genes generate proteins that aid the immune system in distinguishing between the body's own proteins and proteins produced by external invaders. Other genes seem to have less of an effect on a person's overall chance of getting the disease.Other non-genetic variables are thought to have a role in the development of rheumatoid arthritis. Although the process is unknown, several variables may cause the disease in individuals who are at risk. Changes in sex hormones (especially in women), occupational exposure to specific types of dust or fibers, and viral or bacterial infections are all potential causes.

MACHINE LEARNING

Machine learning has emerged as a key technique for data mining and modeling in both medical and IT research. Machine learning is already in use across the globe, with Google's Alpha, Tensor Flow, Microsoft Azure, and IBM's Watson being just a few examples. Clustering, a typical technique of unsupervised learning, was employed in this study to predict rheumatic illness patients in advance.

The empirical examination of an algorithm's behavior was one of the assessment methods described above, and this approach is common enough in machine learning to warrant additional explanation. The laws of combining volumes and the ideal gas law, for example, are empirical in character, which implies that their theories are founded on solid actual facts. This is a positive indication that an increasing number of machine learning researchers are concentrating their efforts on finding similar occurrences in the behavior of learning systems. Many disciplines express such occurrences as relationships between independent and dependent variables. The structure of the information to be acquired and the regularity in the environment are two natural independent concepts in machine learning (e.g., the amount of noise in the data)[10]. For incremental learning techniques, you may change the sequence in which data is given and the environment's stability over time. The majority of natural dependent measures are linked to a performance criteria, such as diagnostic accuracy (for classification tasks) or solution route quality (for problem-solving tasks). However, they aren't the only factors, and finding meaningful independent words and usable metrics is an essential job for machine learning researchers.

Types of Machine Learning

Supervised Learning

Supervised Learning algorithm learns from a known data-set (Training Data) which has labels to make predictions. Regression and Classification are some examples of Supervised Learning.

CLASSIFICATION

Classification determines to which set of categories does a new observation belongs i.e. a classification algorithm learns all the features and labels of the training data and when new data is given to it, it has to assign labels to the new observations depending on what it has learned from the training data.

REGRESSION

Regression is a supervised learning algorithm which helps in determining how one variable influences another variable.

Unsupervised Learning

Unsupervised learning algorithm draws inferences from data which does not have labels. Clustering is an example of unsupervised learning. “K-means”, “Hierarchical”, “Fuzzy C-Means” are some examples of clustering algorithms. Unsupervised learning problems can be further grouped into clustering and association problems.

Clustering:

A clustering problem is where you want to discover the inherent groupings in the data, such as grouping customers by purchasing behaviour.

Association:

An association rule learning problem is where you want to discover rules that describe large portions of your data, such as people that buy X also tend to buy Y.Some popular examples of unsupervised learning algorithms are:K-means for clustering problems and Apriori algorithm for association rule learning problems.

HOW MACHINES DO LEARNS?

The fundamental learning process is the same whether the learner is a person or a computer. It may be broken down into three parts, as follows:

- Data input: Observation, memory storage, and recall are used to give a factual foundation for subsequent reasoning.
- Abstraction: This is the process of transforming facts into more abstract representations.
- Generalization: It is a method of taking action based on abstracted facts.

The most fundamental job for a learning algorithm is to represent raw input data in a structured manner. Prior to this moment, the data is nothing more than a collection of ones and zeros on a disk or in memory, with no significance. During the abstraction phase, the task of giving a meaning to data takes place. The computer summarizes raw inputs in a model, an explicit description of organized patterns among data, during the knowledge representation process. The computer summarizes raw inputs in a model, an explicit description of organized patterns among data, during the knowledge representation process. Models come in a variety of shapes and sizes. Some of these may be known to you. Equations, diagrams such as trees and graphs, logical if/else procedures, and groupings of data are just a few examples.

The machine is seldom given the option of selecting a model. Instead, the learning goal and the kind of data being analyzed determine the model. Training is the process of fitting a certain model to a dataset. To begin, keep in mind that the learning process does not stop with the data abstraction phase. Learning necessitates an extra phase in which the knowledge is applied to future data. Second, the word "training" provides a better description of the actual process of fitting the model to the data. Learning entails a kind of bottom-up, inductive thinking. The term "training" refers to the fact that the machine learning model is imposed on the machine pupil by a human instructor, giving the computer a framework to model after.

The process of transforming abstracted information into a form that can be used for action is known as generalization. Generalization is a rather nebulous and difficult-to-describe process. It was formerly thought to be a search across the full collection of models (or hypotheses) that might have been abstracted during training. In particular, consider a hypothetical set comprising every conceivable hypothesis that might be formed from the data; generalization entails condensing this set into a manageable number of significant results.Bias is an unavoidable byproduct of every machine learning task's abstraction and generalization processes. Every learner has flaws and is prejudiced in some manner; there is no one model that can account for all of them. As a result, the last stage in the generalization process is to assess the model's success, biases and all.

A model is evaluated on a new dataset after it has been trained on an original dataset, and its characterisation of the training data is assessed on how well it generalizes to the new data. It's worth mentioning that a model's ability to fully generalize to every unexpected circumstance is very uncommon. Part of the reason why models fail to generalize properly is because of noise, or unexpected fluctuations in data. Noise in data is produced by occurrences that seem to be random, such as:

- Measurement inaccuracy owing to sloppy sensors that sometimes add or remove a few tenths of a percent from the reading
- Data reporting issues, such as respondents reporting random responses to survey questions in order to complete the survey faster.
- Errors resulting from improper data recording, such as missing, null, truncated, poorly coded, or corrupted values.

Overfitting is an issue that arises from attempting to predict data noise. Because noise is inexplicable by definition, trying to explain it will lead to incorrect conclusions that are difficult to apply to other situations.

Unsupervised machine learning applications

The following are some examples of unsupervised machine learning applications:

- Clustering divides the dataset into groups based on shared characteristics.
- Anomaly detection may help you find out whether there are any strange data points in your collection. It's helpful for detecting shady trades.
- Association mining finds groups of things in your collection that often appear together.
- For data pre-processing, latent variable models are often employed. Reducing the amount of characteristics in a dataset or breaking it down into numerous components are examples.

USING R FOR MACHINE LEARNING

Several of the machine learning algorithms required by R are not included in the basic installation. A wide community of professionals contributed to the program and added the algorithms required for machine learning to basic R. A package is a set of R functions that may be shared among users. For each of the machine learning methods discussed in this book, there are free packages available. In reality, just a tiny fraction of the most popular machine learning tools is covered in this book.

In this work, we provide an approach that builds a resilient random forest classifier with optimum parameters before selecting the smallest number of genes with the highest accuracy in response prediction. We analyze the impact of various parameters on the random forest error rate and propose a technique to choose the optimal parameters in order to build a stable classifier. We find a list of predictive genes using the best parameters. We propose a new clustering-based gene selection approach that ranks genes by frequency to pick the smallest number of genes from this collection. The frequency ranking method guarantees that chosen genes are consistently significant in prediction, while the clustering method picks a limited group of uncorrelated and non-redundant genes with good prediction capacity. The diversity of the best predictive gene lists has already been observed and proven to be dependent on the training set. Despite this heterogeneity, various top gene sets perform well on different sample sets, according to research. To capture this diversity, we utilize random sampling of the RF to find all of the strongest predicting genes.

We tested our method on a collection of 46 Rheumatoid Arthritis patients' whole blood gene expression patterns. Before starting anti-TNF treatment with one of the three authorized drugs: etaneracept, inflixmab, or adalimumab, blood was taken from the patients. After three months of treatment, the patients' reaction to therapy was evaluated. The CRF method found an eight-gene signature before treatment that accurately predicts therapeutic response with 89 percent accuracy, and it has been reproduced with a small independent group of data. This result shows that a molecular diagnosis may be developed for use in the medical treatment of RA patients using anti-TNF therapy.

To demonstrate the broad usefulness of our technique, we used the CRF to three previously published expression data sets and compared feature selection and classification with the recursive SVM (RSVM) method. Both approaches were tested using separate testing sets of data that were not utilized in any stage of the training process or feature selection. The CRF chooses a considerably lower number of features (5-8 genes) than the RSVM (60-80 genes) in all instances, and has superior performance as assessed by the area under the receiver operating characteristic (ROC) curve in the majority of cases (AUC).

DISCUSSION

In recent years, one of the most significant issues in health and medical treatment has been the aging population in our society. Rheumatic illness is more prevalent than any other disease in an aging population, and rheumatism is a musculoskeletal discomfort that reduces patients' quality of life. In terms of quality of life, it is critical to anticipate which individuals may acquire rheumatic illnesses. Clinical data was analysed in order to predict individuals with rheumatoid arthritis in this research. In this work, we utilize machine learning to predict rheumatic illnesses utilizing four variables for rheumatic disease diagnosis, and it will aid in the prediction of rheumatic diseases in the future using artificial intelligence. Nowadays, a vast quantity of data is readily accessible. Machine learning is a subset of artificial intelligence that is used to create algorithms based on data trends and previous data connections. Machine learning is utilized in a variety of areas, including bioinformatics, intrusion detection, information retrieval, gaming, marketing, virus detection, and picture deconvolution.

CONCLUSION

ML algorithms can handle a wide range of data configurations, define context weighting, and discover useful patterns that allow subgrouping or predictive modelling from every interaction of variables accessible for the evaluation of diagnostic and prognostic components. First, machine learning only works if the training data is indicative of the issue to be addressed, contains relevant features, and is large enough to train the model in question. For both technical and practical reasons, this may be difficult to accomplish. Second, in the gathering of sensitive clinical data, privacy is a significant issue, which may restrict the aggregation of all required data. Furthermore, some data is costly to collect, is presented in a variety of forms, and was acquired using a variety of techniques and technologies. Third, professional human judgment is required to evaluate the data, identify any mistakes or issues, and assess the clinical relevance of any results since text-based medical records may be incoherent, distracting, and include technological faults. Finally, agreement on how to integrate and coordinate ML findings with already defined guidelines or recommendations based on conventional statistics should be achieved. A research to predict individuals with rheumatoid arthritis in this study. Rheumatoid arthritis is a disease that has a significant impact on the quality of life of patients in an aging society. However, if the findings of this research can be used to anticipate the onset of rheumatoid arthritis, the quality of life may be improved.

ABSTRACT

Vinasse is regarded as the most significant source of contamination in the sugarcane ethanol business. Vinasse may be used to make fertilizer, although it is deficient in macronutrients and micronutrients. It is, on the other hand, one of the resources with a high biogas generation potential. Vinasse biogas generation offers both economic and environmental advantages. However, since vinasse has a poor carbon-to-nitrogen ratio, it should be supplemented with complimentary materials such as animal manure, organic industrial waste, and lime fertilizers to increase biogas production. Currently, the globe produces 22.4 gigalitres of vinasse, which has the capacity to generate 407.68 gigalitres of biogas. This potential may be thought of as a major renewable energy source. This article provides an overview of the characteristics of vinasse as well as the generation of biogas from it. In addition, a discussion of the best circumstances for biogas production, biogas potential, and the benefits of biogas generation from vinasse is given.

KEYWORDS: *Anaerobic Digestion, Biogas, Methane, Sugarcane, Vinasse*

INTRODUCTION

Fossil fuel energy use 80% of needed energy: environmental degradation and a rising acceleration in the depletion of energy supplies. As a result, finding clean and renewable energy sources is at the top of the global agenda. Biomass is a significant renewable resource that may be used to replace fossil fuels throughout the globe[1]. When compared to other renewable sources such as hydro, solar, and wind, one of the major benefits of energy generation from biomass, such as conversion to biogas, is the lower capital investment required.Biogas generation from organic waste offers many benefits over other options such as incineration, bio-

oil, and other biological products (such as bioethanol, bio butanol, and bio hydrogen, electricity, and biodiesel in this line. Among the benefits are higher energy yields, lower environmental effects, and lower capital investment needs. When the concentration of bio methane in biogas exceeds 40%, it becomes a flammable combination. It is made via a four-stage process utilizing a microbial consortium comprising several bacteria, including hydrolysis, acetogenesis, acetogenesis, and methanogenesis[2]. Clostridium, Cellulomonas, Bacillus, Thermomonospora. Methanogenesis is controlled by a variety of archaebacterial, including Methanococcus, Methanosarcina, and Methanolobus.

For optimum biogas generation, this microbial consortium requires particular parameters, such as a pH of 6–7.5 and a temperature of 35–55 °C. Lignocellulose wastes, household and urban wastewater, and industrial wastewater are the three main sources of biogas. Agro-industrial wastes have a significant potential to pollute the environment due to their global bulk. If these leftovers are released into the environment without being properly disposed of, they may cause pollution and have negative consequences[3]. These untreated wastes contribute to climate change by increasing the amount of greenhouse gases released. The high chemical oxygen demand (COD) of these untreated wastes also provides ideal circumstances for pathogenic fungus and bacteria to thrive. Due to the presence of suspended particles, ionic matter, color, and odor, dumping industrial wastewater in nature has a variety of detrimental impacts on the ecosystem. The organic content of this effluent may be substantially reduced by aerobic or anaerobic treatment. To breakdown soluble organic material, most industrial wastewater treatment facilities utilize anaerobic digestion. The generation of bioethanol from sugarcane is one of the greatest options for replacing fossil fuels[4]. Still, one of the issues associated with bioethanol production is the treatment of vinasse wastewater. Biogas produced from sugarcane wastes offers a large potential for energy generation. Biogas generation is a straightforward technique for reducing pollution, supplying bio fertilizer, and generating a clean and inexpensive fuel. Sugar crops (e.g., sugar cane, molasses, sweet sorghum, and grapes), starch crops (e.g., corn, wheat, rice, cassava, and barley), tuber crops (e.g. potato and cassava), dairy products, and cellulose materials (e.g., rice straw, bagasse, wood, and municipal solid waste) can all be used to make bioethanol.

Agricultural leftovers and industrial byproducts are the two major kinds of waste generated during the manufacture of sugar and bioethanol from sugarcane. The former is made up of sugarcane that has been burnt or crushed during the harvesting process[5]. Ash, bagasse, filter cake, molasses, and vinasse are the five kinds of waste as well as the primary product. Vinasse is the most contamination-prone of these wastes in bioethanol production. After alcohol synthesis, an estimated 88 percent of molasses is excreted. Due to the sensitivity of alcohol-producing yeasts to concentrations of more than 9–11 percent alcohol, a lot of water is required to dilute alcohol, which results in a lot of effluent. A fermentation procedure at the maximum concentration of the original sugar may be used to minimize the huge quantity of effluent. This may be accomplished by employing yeasts that can withstand high alcohol concentrations. Some of the output effluents are returned to dilute the molasses in order to accomplish this goal[6]. This procedure may handle up to 20% of the return flow, but if done too often, the quality of the molasses would suffer. According to a study of the literature, vinasse is the most common source of contamination in the production of bioethanol, and its conversion to biogas may minimize contamination while generating clean and cheap biofuel. This article examines the production of vinasse, its characteristics, and the biogas process's generation from vinasse, as well as its benefits.

Beet, sugarcane, sweet sorghum, grape, and agave soluble solids are used to make vinasse. The characteristics of vinasse are mostly determined by the raw materials used and the circumstances under which the alcohol is produced. The kind of molasses utilized, the method of fermentation

and distillation employed, and the variety and maturity of sugarcane all influence the uniqueness of sugarcane-based vinasse. Sugarcane vinasse has a greater COD than vinasse made from other sources including sugar beet, sweet sorghum, grapes, and agave.Most, stillage, thin stillage, distillery wastewater, distillery spent wash, and distillery slope are some of the names given to it [7]. It is a liquid generated in the rectification and distillation unit of the bioethanol manufacturing process, which is shown. Vinasse makes up 80% of the raw materials needed in the production of alcohol. Vinasse is produced at a rate of 8–20 L per liter of ethanol in a conventional alcohol plant. Brazil generates half of the world's total sugarcane-based bioethanol. Brazil, India, China, Thailand, Pakistan, Mexico, Colombia, Indonesia, the Philippines, and the United States are the world's top sugarcane growers, contributing 739.000, 341.200, 124.500, 100.100, 63.800, 61.200, 34.900, 33.700, 31.900, and 27.900 Mt per year, respectively[8]. 38.1, 17.3, 6.1, 4.3, 3.2, 2.8, 1.8, 1.3, 1.1, and 1.4 percent, respectively. The majority of bioethanol made from sugarcane is generated in Asia and South America. Africa, Asia, Central America, and South America produce approximately 0.23, 0.82, 0.18, and 0.37 gig liters of bioethanol annually, respectively. Bioethanol is generated at a global rate of 1.6 gig liters per year, resulting in 22.4 gig liters of vinasse. From 25 billion liters of bioethanol, Brazil generated 325 billion liters of vinasse in 2009. In 2019, 588 billion liters of vinasse are expected to be produced in Brazil. Vinasse is a tough and abrasive effluent produced from ethanoic distillation at temperatures ranging from 65 to 107 °C and pH levels of 3 to. The temperature of the distillation column is mostly determined by the technology employed, which is primarily Barbet and Other systems[9]. These commercial operations may be carried out under vacuum pressure at a low temperature of 65 °C, while atmospheric distillation requires a high temperature of 107 °C. The pH is also influenced by the circumstances of cane growth and processing. The decrease of the vinasse pH may potentially be due to ethanoic fermentation contamination by acid-forming bacteria.Phytotoxic, antibacterial, and recalcitrant chemicals such as phenols, polyphenols, and heavy metals are also found in vinasse[10].

DISCUSSION ON BIOGAS PRODUCTION FROM SUGARCANE

Vinasse is composed of 93–97% water, 5% organic matter (sugars and carbs), and 2% inorganic insoluble particles. It has a high water solubility. Sugarcane molasses contains 2% dark brown pigments called melanoidins, phenolic chemicals (tannic and humid acids), caramels, and furfurals, which stain vinasse and inhibit microbial development. Organic matter makes up around 75% of the solids in vinasse. Calcium hydroxide may be used to decrease the quantity of volatile solids in vinasse. Vinasse has the following density, viscosity, conductivity, boiling point, specific heat capacity, and thermal value: 1.031 kg/L, 0.00138 Pa s, 16.4 dS/m, 100.25 °C, 0.934 Cal/g.C, and 3.39 Cal/g. Vinasse is a mixture of organic matter and solid minerals that results from the distillation of alcohol and contains some residual sugars, alcohol, and non-volatile chemicals. Organic matter, which includes non-fermentable substances in molasses such as sugars (glucose and fructose), fermented products that cannot be separated during distillation (glycerol and organic acids), and yeast residue that cannot be separated through the industrial process, are the major components in vinasse. Alcohols, aldehydes, ketones, esters, acids, and sugars are among the organic substances found in vinasse. Potassium, calcium, and sulfate ions, dead yeast cells, minerals from microorganism metabolic processes, alcohol and residual sugar, insoluble mineral compounds, and mineral volatile compounds are the most common mineral compounds.Propionic acid is one of the volatile fatty acids present in vinasse, which microorganisms degrade rapidly. Potassium (due to potassium in molasses has the greatest concentration among the vinasse macronutrients, followed by sulfur, magnesium, nitrogen, calcium, and phosphorus. The macronutrients, such as magnesium for clarity and calcium for carbonation, are mostly added during the sugar manufacturing process. Iron has the greatest concentration of vinasse micronutrients, followed by manganese, zinc, and copper at lesser

amounts. Vinasse includes significant quantities of sulfate due to the use of sulfuric acid to decrease pH during fermentation and yeast formation. Vinasse has 4–10 times more sulfur than the optimal concentration for biogas generation.

Due to the production of H2S, such high sulfur levels resulted in the stoppage of digestion. High H2S concertation has a detrimental impact on biogas production by disrupting methanogenic bacteria, competing with methanogenesis for sulfate reduction, and limiting trace element bioavailability. As a result, lowering H2S generation should be addressed in order to enhance biogas output. Heavy metals, including as chromium, copper, nickel, and zinc, are also found in vinasse, which are produced during the molasses processing. Sugarcane molasses vinasse has more sulfate, potassium, and iron than other vinasse sources. The chemical components of sugarcane vinasse from various nations are given. Coccus, Curve rod, Filament, Methanosat, Methanosarcina, Fluorescent rods, and S. cerevisiae are among the bacteria identified in vinasse, with the last two being methanogenic microorganisms.According to vinasse genotyping experiment, methanobacteriales and methanosarcinales are the best methanogenic microbes for producing methane from vinasse under optimal circumstances in a modified UASB reactor. They are more active and adaptive in vinasse-rich environments. In contrast to Methanosarcina, Methanothrix, being a methanogenic bacterium, is more sensitive to poisonous chemicals found in vinasse. The development of Methanosarcina is caused by the presence of magnesium and calcium ions in vinasse. Magnesium and calcium are two substances that are required for all microbial development. Magnesium, calcium, and substrate concentrations all influence the shape of methanosarcina. These variables allowed for morphological modification and interconversions between pseudosarcinal aggregates and individual coccoid cells. The impact of calcium and magnesium on methanosarcina development was studied. Adding 0.5 g of CaCl2.2H2O and MgCl2.6H2O per liter resulted in a three-fold rise in methanosarcina concentration, according to the findings.

Bioethanol manufacturing facilities are one of 17 industries that pollute the environment severely. Vinasse produces greenhouse gases such as CH4, N2O, and CO2, with methane accounting for 99.8% of the total. These gases create a number of issues, in addition to global warming caused by changes in the environment's chemical and physicochemical characteristics. Adding heavy metals to the soil, such as lead, zinc, and copper, increasing electrical conductivity and total dissolved solids, and decreasing plant germination (negative impact on microbial activity are other issues. Furthermore, when vinasse is released into the environment, it causes toxicity in surface and underground water due to high concentrations of solids and hard constituents such as phenols and polyphenols (8000-10,000 mg/L), corrosive organic matter content of indole 3-methylindoleand increased eutrophication due to high nitrogen and phosphorus content. Vinasse colored compounds reduce sunlight permeability in rivers and lakes, reducing photosynthetic activity and dissolved oxygen concentration (due to high temperature of vinasse) in water, resulting in hazardous conditions for aquatic life and disruption of plant and aquatic animal life due to reduced photosynthesis. Many fish are killed by the “cowshed-fly” Stomoxyscalcitrans as a consequence of the widespread use of vinasse in fields and its penetration into groundwater. Vinasse is also poisonous due to its low pH and metal content. It's 100 times more toxic than sewage from homes. Vinasse may be kept at temperatures below 4 °C to minimize microbial activity.

On vinasse, an Allium cepa test revealed no germination potential. Vinasse has been shown to have a 50% cytotoxic. When it comes to vinasse storage, the methane release rate in open channels is 1.36 kg CO2eq m3, which is 620 times higher than in closed reservoirs or settings. This is owing to the difficulty of fermenting it in the confined reservoirs. Because of the pollution and strong odor caused by vinasse decomposition, it should be disposed of outside of inhabited regions. Vinasse's darkness creates a filthy, immature atmosphere. Humans dislike the

odor of vinasse, and its presence in drinking water causes an epidemic of malaria, and schistosomiasis. Meloidogynejavanica, M. incognita, and Drosophila melanogaster worm eggs may grow in it. Each liter of vinasse pollutes the environment in the same way as 1.43 people pollute the environment. Vinasse is used in the chemical industry to make organic acids, Bacillus subtilis surfactants, and amino acids, among other things. 150m3/ha vinasse equals 61 kg/ha nitrogen, 40 kg/ha phosphorus, 343 kg/ha potassium, 108 kg/ha calcium, and 80 kg/ha sulfur. Vinasse is also used to make hydroponic culture, protein, and material compost as a fuel, having a thermal value of 12560–15070 kJ/kg. Vinasse is utilized in civil construction and cattle and poultry feed (because to its high nutritional content), as well as source materials for bacteria and fungi to produce lipids and road folding and mulching.They are more active and adaptive in vinasse-rich environments. In contrast to Methanosarcina, Methanothrix, being a methanogenic bacterium, is more sensitive to poisonous chemicals found in vinasse.

The development of Methanosarcina is caused by the presence of magnesium and calcium ions in vinasse. Magnesium and calcium are two substances that are required for all microbial development. The shape of methanosarcina is influenced by magnesium, calcium, and substrate concentrations. These variables allowed for morphological modification as well as interconversions between pseudosarcinal aggregates and individual coccoid cells. It can also be used to produce single-cell protein and calcium-magnesium acetate for the production of various bio-products (e.g., enzymes, chitosan, astaxanthin, planthormones, biopolymers, alternan, pullulan), algal production (e.g., Chlorella vulgaris and Neochlorisoleoabundans, and yeast production that requires high energy and the addition of ammonium and magnesium vinasse does not meet the requirements for direct use in soil. one of the most frequently utilized techniques. In addition to reducing COD and total organic carbon (TOC), the ozone pre-process and UV light may increase 20 percent of generated methane and reduce phenolic chemicals and color. At normal circumstances, the ozone preprocess may decrease phenolic compounds by 65% and color combinations by 80%, raise methane gas from 250 to 284 ml/gCOD, and reduce COD removal by 79 to 81 percent. The methane generation in AD treatment was 0.315 m3CH4/kgCOD, with a COD removal efficiency of 75.1 percent, according to a test conducted at mesophilic temperature to assess the effectiveness of treating vinasse using anaerobic digestion (AD) followed by ozonation. In a bubbling column, the anaerobically digested effluent was further treated with ozone. COD removal efficiency was 99.2 percent with 100 mgO3/L, whereas color removal efficiency was 99.3 percent. The AD process was carried out in a laboratory-scale upflow anaerobic filter reactor (UAFR) that ran continuously at 29 degrees Celsius. At 10 kgCOD/m3.day and a 5-day HRT, stable conditions were achieved. Evaporation can concentrate vinasse, which may subsequently be utilized to generate energy in boilers. Although this technique is utilized in Iran, it is not used to generate electricity. Furthermore, coagulation-flocculation, electrocoagulation, and ultra-sonication have all been employed to cure vinasse, all of which demand a lot of energy.

Bioprocessing, advanced oxidative processes, AD, and chemical-based procedures are all examples of vinasse treatment techniques. Oxidation and chemical reactions, AD, and microbial fermentation are among the techniques that are efficient in reducing the organic and mineral load. Wind and sun radiation evaporate the water from vinasse in fermented lagoons, and the sludge is discharged, resulting in greenhouse gas emissions and environmental pollution. In contrast to certain nations, such as Brazil, some countries, like as Iran, do not utilize vinasse as a fertilizer in their fields due to soil salinity. Anaerobic digestion has been proposed as a biodegradation technique for handling organic wastes on a wide scale. The goal of anaerobic digestion is to turn trash into two types of useful and necessary materials: biogas and high-quality crop fertilizer. This procedure is carried out by a symbiotic community of microorganisms. Methane, carbon dioxide, ammonia, water, and bacterial cells are all examples

of complex organic molecules that are physiologically transformed to a variety of chemicals. When compared to aerobic digestion, it generates 10% less sludge. Vinasse has a strong anaerobic digestion capability. Vinasse anaerobic digestion may be used to stabilize organic waste and generate biogas as well as the energy required to dry yeast at the facility or distill ethanol. Sulfate and the majority of organic debris are eliminated during anaerobic digestion of vinasse, while numerous organic volatile chemicals and minerals potassium, nitrogen, and phosphorus are separated. Anaerobic digestion has been proposed as a biodegradation technique for handling organic wastes on a wide scale. The goal of anaerobic digestion is to transform trash into two types of useful and necessary materials: biogas and high-quality crop fertilizer. This procedure is carried out by a symbiotic community of microorganisms. Methane, carbon dioxide, ammonia, water, and bacterial cells are all examples of complex organic molecules that are physiologically transformed to a variety of chemicals. When compared to aerobic digestion, it generates 10% less sludge. Vinasse has a strong anaerobic digestion capability.

CONCLUSION AND IMPLICATION

The characteristics, significance, and environmental effects of vinasse, as well as its treatment using anaerobic digestion to produce biogas, are discussed in this article. Vinasse, a liquid byproduct of the rectification and distillation of bioethanol from sugarcane, is one of the world's biggest sources of industrial effluent. Anaerobic digestion is one of the most efficient and promising methods for reducing vinasse's harmful environmental impacts. Vinasse, on the other hand, cannot be effectively converted to biogas as a single substrate because it lacks sufficient macronutrients and micronutrients and has a poor carbon-to-nitrogen ratio.As a result, co-digestion should be used to compensate for vinasse's nutritional and carbon to nitrogen ratio deficiencies.

ABSTRACT

Determination of the fallout of condensate on the inner surface of the fence when exposed to aerosols. Aerosols present in the production environment significantly affect the change in relative humidity and condensation on the inner surface of the fences and their effect must be taken into account in the calculations.

KEYWORDS:*Changing Temperatures, Humidity Regime, Moisturizing The Enclosing Structures, Saline Material, And Capillary Condensation.*

INTRODUCTION

In industrial buildings with aggressive environments, external walls are used in qualitatively different conditions compared to walls that are only influenced by moisture and temperature gradients.

In accordance with building codes and regulations, industrial premises of most modern chemical factories can be classified as premises with normal or even dry temperature and humidity conditions. Numerous field studies of the temperature and humidity regime of the air at potash plants confirm this statement [1-5].

However, in many cases, the walls of such buildings are covered with efflorescence and wet spots, which indicates an unfavourable humidity regime. Analysis of samples taken by the thickness of the clay brick walls shows that in some buildings the average humidity at the end of the moisture accumulation period exceeds the allowable 5%, and the local maximum humidity is higher. In the warm season, the walls do not have time to dry out. A similar picture is observed in walls made of expanded clay concrete panels with a protective layer of heavy concrete [7-12].

MATERIALS AND METHODS

The increased humidity of structures in the presence of salts leads to the destruction of the wall material, especially from the outer surface, which is exposed to sharply changing temperatures. In addition, the concentration of salt dust in the outdoor air often exceeds the concentration of dust in the indoor air [13-19]. The degree of salinity, the design of the wall and some other factors affect the process of moisturizing the enclosing structures and the nature of the distribution of moisture along with the thickness of the wall. However, with the correct choice of the structural solution of the wall, the decisive influence of the salt solutions contained in the thickness of the fence on the humidity regime is undoubted, since in the pores of the wall material there are solutions of salts with physicochemical properties that differ from water.

The presence of chloride salts in the thickness of the fence increases the hygroscopicity of materials (the ability to absorb moisture from the air) [20-27]. The sorption properties of building materials are determined by the nature of the connection between moisture and the surface of pores and capillaries. The amount of adsorbed moisture in the presence of salts will depend not only on the temperature and humidity conditions of the environment and the nature of the material to be moistened but also on the physicochemical properties of salts and their amount in the pores of the material. In small pores of saline material, capillary condensation occurs when the relative humidity of the air is much lower, depending on the chemical composition of the salt and the concentration of the solution. Determination of the duration of exposure to condensate caused by aerosol hygroscopicity can be considered by the example of assessing the inner surface of the enclosing structure in buildings with aggressive environments.

The calculation of the time during which during the cold period of the year condensation will fall on the inner surface of the fences is based on the determination of the dew point temperature. The result of the calculation can serve as an approximate estimate of the time of exposure of the liquid phase to the protective coating of the fence from the inside since it is made with the following assumptions: when determining the outside air temperature, which causes condensation on the inner surface of the wall, it is assumed that the temperature of the inner surface of the wall changes instantly after the change in the outside air temperature, i.e., the thermal inertia of the wall is not taken into account. The assumption made leads to an inaccuracy in the estimate of the total time of condensate precipitation in comparison with the actual values in the direction of increase [28-34].

The total time of exposure to the liquid phase during the cold period of the year on the protective coating is determined, without taking into account periodic increases in the outside air temperature and corresponding to the increase in the temperature of the inner surface of the wall, causing interruptions in condensation, which has a positive effect on the service life of the protective coatings. Consequently, the frequency of condensation is taken into account only in the annual cycle of changes in the outdoor temperature.

The thermal engineering calculation of the fence is carried out following the chapter of SNiP on construction heat engineering. It is desirable to take real values obtained based on field studies as parameters of the internal air (temperature, humidity and aerosol properties). In the presence of hygroscopic aerosols in the air of the industrial premises, the nominal relative humidity of the air, determined by the formula

$$\varphi_y = \frac{\varphi_в}{\varphi_г} 100\%,$$

Where $\varphi_в$ - is the relative humidity in the room,%;

$\varphi_г$ -Hygroscopicity of aerosol,%;

Depending on the temperature of the indoor air tв and the relative humidity of the indoor air, the absolute relative humidity of the air and the relative temperature of the dew point are determined. according to tables of values of maximum vapour pressure. The maximum outside air temperature at which condensate will fall out on the inner surface of the fence, under stationary heat transfer conditions and the above assumptions, can be determined by the formula

$$t_H \le t_в - \frac{t_в - \tau_{ру}}{R_в} R_0$$

wheretB - indoor air temperature, ℃

$\tau_{ру}$ -conditional dew point temperature of the inner surface of fences, ℃

$R_в$– heat resistance$м^2$.ч. ℃/ kcal

The time in hours during which condensation will fall on the inner surface of the fence can be determined from the data of the SNiP chapter on construction climatology and geophysics.

RESULTS

Thus, it has been shown that aerosols present in the production environment significantly affect the change in relative humidity and condensation on the inner surface of the fences and their effect must be taken into account in the calculations. The studies carried out have established that the calculation of the time during which condensation will fall on the inner surface of the fences during the cold period of the year should be based on determining the dew point temperature, taking into account the assumptions of not taking into account the thermal inertia of the wall and the frequency of condensation.

How to care for concrete in the summer. If you decide to concrete any structural element in the summer, then you should understand that in summer there is high temperature and low humidity. That is why in the summertime the concreted area is covered with burlap and periodically moistened by pouring water every 2-3 hours. If the weather is not very hot, then it is worth watering every 10-12 hours. It is necessary to water the concrete within three days. This concrete care is needed in order to avoid the evaporation of water in the concrete solution itself since, without water, concrete will crack and corrode. In a humid environment, concrete gains greater strength.

How to care for concrete in winter. At a temperature of + 5-10 degrees, the hardening of concrete is significantly reduced. And at temperatures below 0, it stops. Therefore, there are three ways to heat concrete in winter. The first of these is the "thermos method". The concrete is covered with a film, and steam or warm air is allowed under this film. Because of what the concrete heats up and becomes a humid climate, which favourably affects the conditions for its freezing. The next method is "electrical heat treatment", that is, electrodes are inserted into the concrete around the perimeter and closed in one circuit, after which a current is started. And the most common way is the third - the introduction of chemical additives into concrete. There are various chemical additives that "make" the concrete mixture harden. The most common additives are calcium chloride and sodium chloride, sodium nitrate and urea. All supplements can be purchased at any hardware store.

CONCLUSION

How to choose heavy concrete. If your structure or structure is located in a humid area or a humid environment, corrosion-resistant heavy concrete should be used. So you need to cover the concreted place with dense ceramic tiles or process it with liquid glass, for complete confidence that the concrete will not corrode. If your structure or structure will be located in a room or area

with a high temperature, you should use heat-resistant heavy concrete. It is also worth revealing it with ceramics or heat-resistant materials.

ABSTRACT

The article describes measures to replace foamed foam insulation, which is used as a thermal insulator in the construction and installation of "warm floors" for heating rooms, with non-woven materials obtained from relatively inexpensive fabric waste. In the construction of "warm floors" for heating houses in the cold season, during their installation, under the pipes are insulated with aluminium foil on the paralon to insulate from the heat. At market prices, such bedding costs $ 1.2-1.4 per square meter.

KEYWORDS:*Nonwovens, Yarns, Fabrics, Knitwear, Fabric, Fabric, Felt, Fibre Mats, Glued Fabrics, Technology, Mechanical Technology, Physicochemical Technology, "Warm Floor".*

INTRODUCTION

In the construction of "warm floors" for heating houses in the cold season, during their installation, under the pipes are insulated with aluminium foil on the paralon to insulate from the heat. At market prices, such bedding costs $ 1.2-1.4 per square meter.

The main function of these linings is to prevent the hot water energy moving in the pipe from passing to the bottom of the concrete floor, which saves on the cost of heating the room. These mats are mainly made of artificial password material [1-7].

Typically, these floors are covered with heating pipes and covered with a 7-8 cm layer of concrete. Such insulation coatings are not subject to any mechanical effects, ie they remain between the concrete floor. Therefore, it would be appropriate to replace these beds with relatively inexpensive rock beds from waste recycling [8-11]. For this purpose, we recommend recycling artificial and synthetic fabrics from clothing and using them as insulation.

MATERIALS AND METHODS

Non-woven fabrics are already being developed using various technological methods.

Many types of nonwovens are made from fibre mats. The properties and quality of fabrics depend on the properties, physical and mechanical properties and composition of the raw materials that make up this carpet.

The bedding we want to recommend is crushed on special machines before being made and shaped into fibres

Typically, non-woven fabrics are made by mixing several types of fibres of different qualities. Fibres with different properties should be mixed well so that they are evenly distributed in the fabric [12-18].

For maximum purification and mixing, the fibres should be separated into small groups. The process of making the fibres like this is called titration. From the above considerations, it is clear that the process of grinding, cleaning, mixing must be repeated in a certain sequence and continue uninterrupted.

The processing of man-made fibres consists mainly of grinding and mixing processes. They have few defects and do not require special cleaning. The processing technology is organized according to the type and linear density of the fibre. Coarse chemical fibres are made in wool processing equipment. Fine chemical fibres (100-200 m_{tex}) can be made in cotton fibre grinding equipment. Synthetic fibres require faster vibration than synthetic fibres. In the manufacture of fabrics from a mixture of several types of fibres, they must be cleaned and blended before mixing until the volume density is uniform. The fibres are redistributed evenly so that they are evenly redistributed in the mixture, ie the proportion of each type of fibre in an arbitrary surface or volume corresponds to the specified norm. no matter what product is produced. The splitting process is done to break up the fibres into smaller pieces.

The fibres are crushed by pinching or by repeatedly hitting the layer hard. Pinching is done using pegs, needles or gears with a toothed surface. In this method, the fibres are divided into sections by unilateral or simultaneous bilateral action.

Strong and repeated blows to the fibres are also referred to as beating. In this method, the fibre layer is pulverized by beating with a beating drum with a knife. Free-kicking of fibres is also used. The essence of the process is to break up large pieces into smaller pieces.

Grinding is done on grinding machines. The main drum and rollers of the machines are mounted on the surface of the rollers with bent ends. The coupling is carried out first with the head drum holding the tuft held by the supply cylinders, and then between the drum and the working pair (Fig. 1).

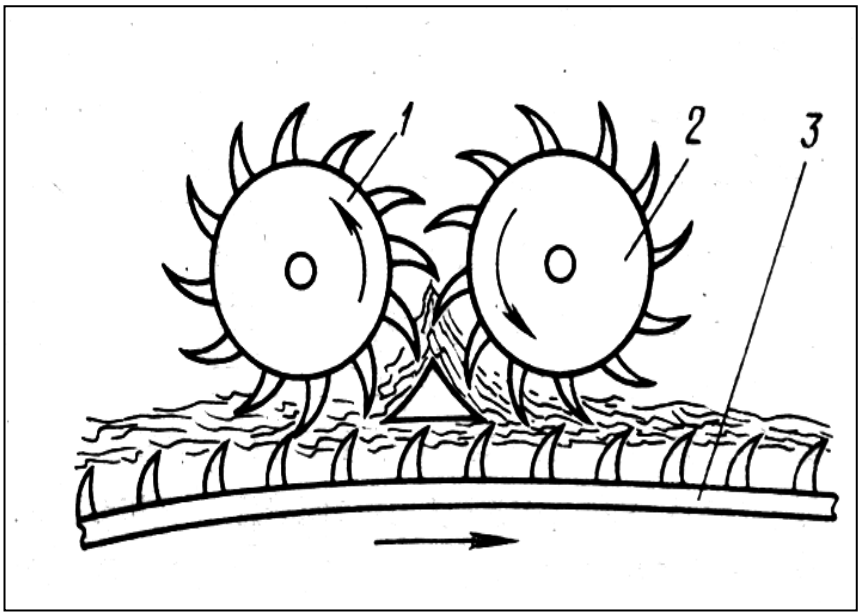

Figure 1 Tightening with working rollers

The fibres in the 3 teeth of the drum are crushed by the relatively slow rotating roller 1 and broken into small pieces. The fibres picked up by the working roller are separated by the cleaning roller 2 with the pegs facing in the opposite direction and transferred back to the main drum. The distance between the drum and the rollers is negative, ie the pins of the rollers are between the pins of the drum [1].

The essence of the mixing process is to evenly distribute the fibres of each type and with different properties in the resulting semi-finished product. There are random and orderly distribution methods for mixing fibres, which are also referred to as unorganized and organized methods, respectively.

Use the soaking method we recommend to create the mattress

The purpose of the impregnation process is to insert the liquid binder into the bed so that the fibres are evenly distributed. As a result of soaking, the mass of the fibre bed increases due to the binding glue [3].

Here's how to put one together for use with your non-woven fabric. In this case, as usual, the pieces of fabric are crushed in a shredder. The resulting product is spread on a scraper to form a paste. The resulting bedding is transferred to a belt conveyor. Before that, a piece of foil equal to the width of the drop from the roll is written on the conveyor. This fortune-telling is covered with a sheet of paper. The speed of the belt conveyor must be equal to the speed of the bed.

The bed continues to move on the conveyor belt, which is formed by recycling the waste on the falcon. Melted polymer melt or liquid bitumen is applied to the fibres from the nozzles mounted on the conveyor. The belt is then passed between the calibration drums mounted on the conveyor during the conveyor movement and pressed to the required thickness. It is then cooled in the air and rolled into a roll. The cost of this mattress is 50-60% cheaper than the password

CONCLUSION

In the cold season, instead of the foam floor used in the installation of "warm floors" for heating rooms, it is possible to achieve great economic efficiency by using non-woven fabrics, which are produced locally using fabric waste.

ABSTRACT

This paper assesses and investigates the fundamental sorts of organization geographies which incorporate the transport, star, ring and lattice topology. This article besides examines every topology's points of interest and weaknesses when utilized. A rundown of investigation was likewise made in an even structure to gather and make it more obvious things. From that point forward, the paper talks about various circumstances where a specific topology can be used.This paper discuses about the Organizations with more resources are already able to afford the expense of the most current advances, but they may still choose for the conventional if they need it. Businesses can be categorized according to their capitalization.This kind of geography is well-liked in small businesses since it is simple to use and understand.

KEY WORDS: *Network Topologies, Wired Network, Microenterprises.*

INTRODUCTION

Nowadays, wireless connections are already utilized but it does mean that everyone is using this. There are still business entities that could not afford to use this type of systems and so they prefer to use the wired connections. Wired connections include the Local Area Network. This is a computer network that interconnects devices within a limited area such as a residence, school [1], laboratory, university campus or office building. This investigation may unquestionably profit individuals from microenterprises. Others organizations having higher measure of resources would already be able to bear the cost of the most recent innovations however they can still pick with the traditional in the event that they need businesses may be classified based on

the amount of capitalization. In the Philippine context, according to the Republic Act No. 9178, we have the following classifications shown on Table 1 [2].

TABLE 1: THE PHILIPPINE CONTEXT, ACCORDING TO THE REPUBLIC ACT NO. 9178.

Classification	Bracket
Micro	Below Php 3,000,000
Small	3,000,001 - 15,000,000
Medium	15,000,001 - 100,000,000
Large	Above 100,000,000

1.1 Network Topology Analysis:

Bus Topology:

This kind of geography is solid in little organizations and it is anything but difficult to utilize and comprehend. This additionally requires minimal measure of links to interface the PCs together and it's anything but difficult to expand [3]. In view of the way that any PC in the organization can communicate information whenever, network traffic can hinder a transport. Likewise, every association between two links can fall apart the electrical sign. In this kind of geography, the transport setup can be hard to track down and can make the entire organization quit working [4].

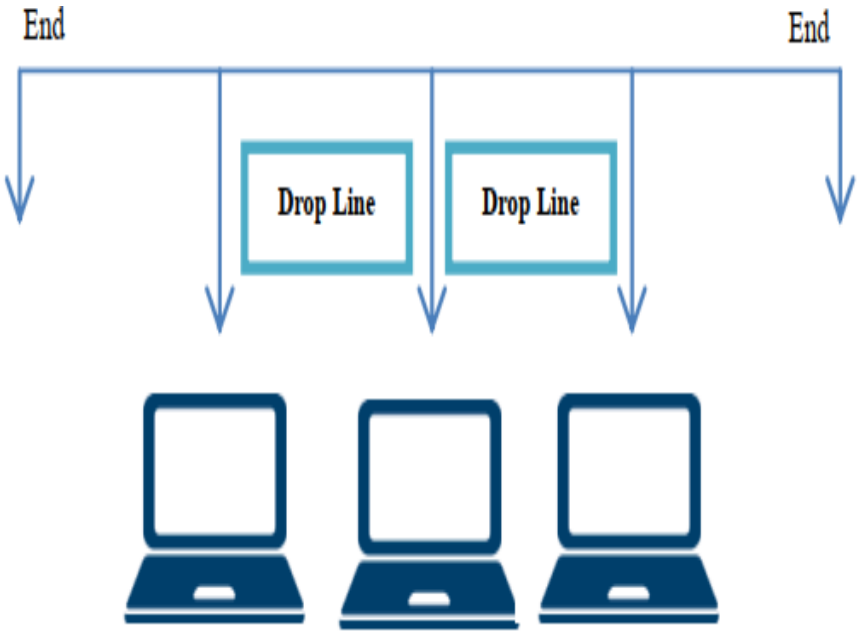

Fig 1: Bus Topology

Star Topology:

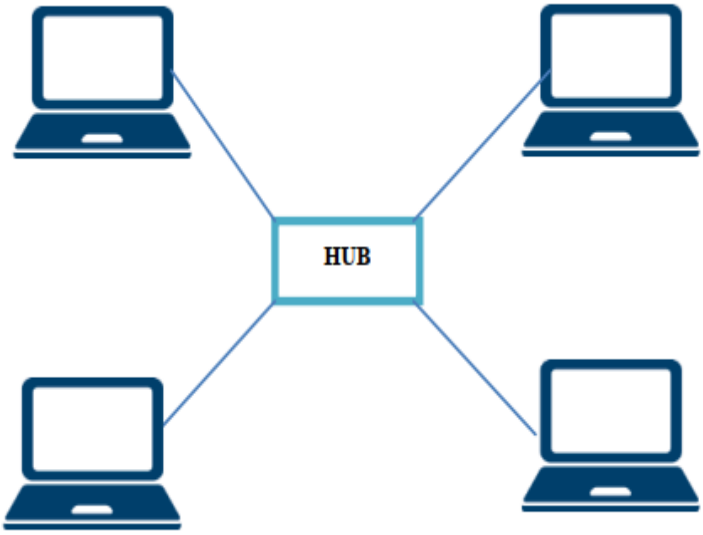

Fig 2: Star Topology [5].

In a star geography, on the off chance that one of the PCs comes up short, it doesn't influence the others and this likewise adds to its great exhibition. The focal point of a star network is a decent spot to analyze network shortcomings and on the off chance that one PC falls flat, the entire organization isn't upset. Substitution or evacuation of gadgets can be effortlessly done[6].

This kind of geography is costly to introduce as it requires more link, it costs more for all organization links should be pulled to one essential issue. This requires more link length than different sorts of systems administration geographies. Since the organization relies on the center point, or the focal hub, in the event that it neglects to work, at that point the entire organization likewise neglects to work [7].

Ring Topology:

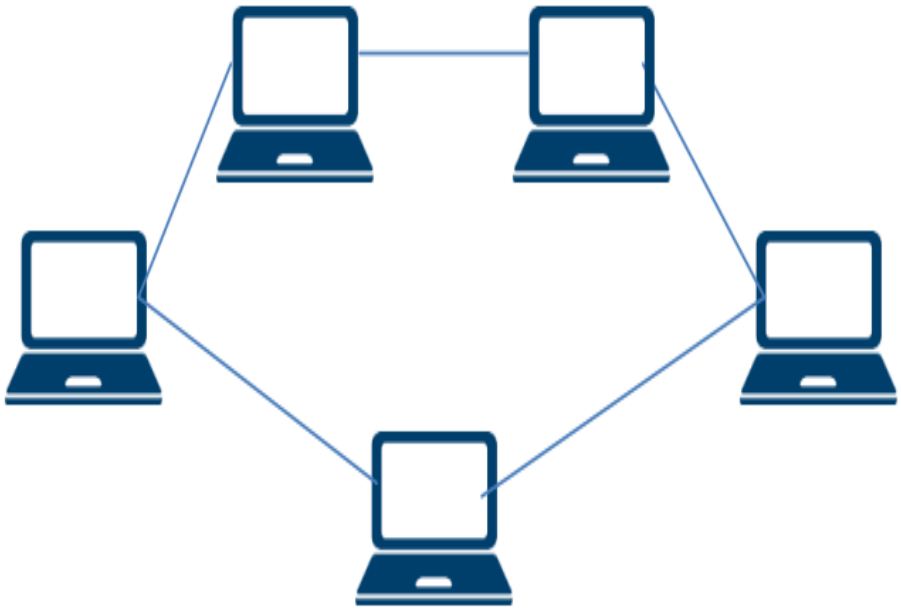

Fig: 3 Ring Topology [8].

A logical or overlay topology is created by combining the work and application layers. The underlying structure of a network affects its communication. This has an effect on protocol performance as well as routing behavior and complexity. It's crucial to choose the right topology for simulations, analytical investigations, and experimentation. Take a look at Figure 4 as an example. Both scenarios depict a local area network that links end devices to the Internet via routers, but the topological characteristics differ. As a consequence of the protocol assessment, totally different findings may be obtained. A routing protocol's failover methods,

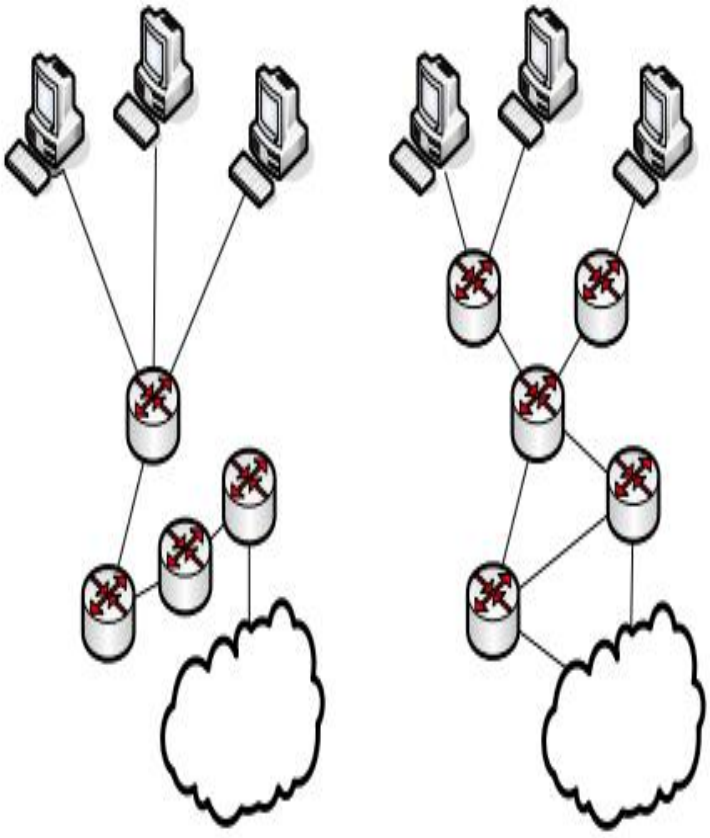

Figure 4: Non-redundant network and redundant network.

For example, cannot be monitored for a configuration. The topology of the network and its characteristics are critical components in the assessment of protocols and systems. They should be selected based on the characteristics of the issue being studied. As a result, clarifying the situation in which the protocol will function is the first step in choosing an acceptable topology. However, in many instances, the underlying network's characteristics are unclear or just loosely specified. As a result, there is a trend to use network measurement to enhance topology modeling. Working with actual data, particularly for big, dynamic networks like the Internet, has unique challenges. To begin with, retrieving actual data for such structures is a difficult job. Second, each measurement is just a snapshot in time, and it may become outdated fast. Furthermore, collections of really huge sizes may be difficult to parse with the memory and CPU cycles presently available. As a result, rather than addressing the issue to a specific network topology, the whole topology space should be investigated.

In this type of topology, the ring network offers high performance for a small number of workstations or for larger networks where each station has a similar workload. The ring networks can also span longer distances compared to other types of networks and these are also easily extendable. Unlike a bus topology, there is no signal loss in Ring topology because the tokens are data packets that are re-generated at each node. This sort of geography costs a lot of cash, time and exertion for its establishment. In the event that one PC comes up short, it can influence the entire organization and it is hard to track down flaw in the organization. The entire framework is disturbed when PCs are being added or supplanted in the organization. This is much slower than an Ethernet network under typical load.

There are many degrees of abstraction in the modeling process. The structural characteristics of a network are formed by a network topology model. Due to indication, dedicated instances of network equipment such as various kinds of routers, switches, and end system nodes are ignored. The second phase 'eliminates' and subsumes any things that are transparent to the layer under observation. We'll concentrate on the local routing structure in this case. As a result, switches will be eliminated, and end devices will be integrated into a single domain. Our network currently consists of routers, end user domains, and an inter-network link. The inter-network link as shown does not contain any further information from a structural standpoint. The last phase converts the physical network into an abstract graph (see Figure 5). Edges and vertices are represented by nodes and links, respectively.

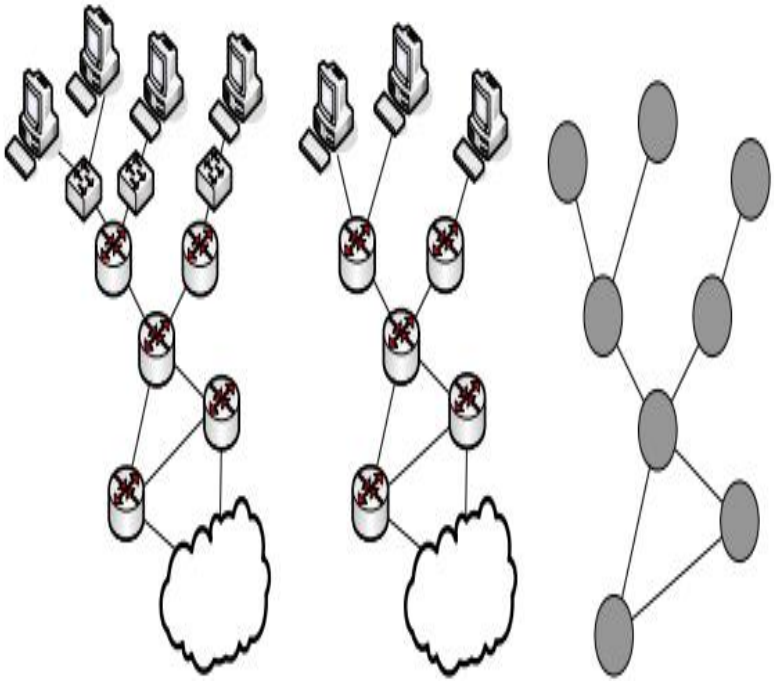

Figure 5: Redundant Network, Redundant Network and Graph Representation.

REVIEW OF LITERATURE

There have been many paper published in the field of network topology among all those paper a paper titled "A Review-Analysis of Network Topologies for Microenterprises by Francis Pol Lim discussed the network topology analysis, bus topology, advantage and disadvantages of bus topology, star and ring topology and its advantage disadvantage, mesh topology and its advantage and disadvantage, discusses the choosing network topology for business, also give block diagram and their algorithm of different topology and their usages in different application [9]. Matthias Wählisch studies Network topologies are an important component of data transmission. They explain how network elements are directly linked to one another and, as a result, how data may flow. This kind of node relationship structure may be constructed on several levels, culminating in a physical or logical structure.

Topology. The rst will be built while using a physical medium to link devices. Data interchange may be organized on top of this structure through the network and application layer, resulting in a logical or overlay topology [10].

DISCUSSION

This paper discus about the Organizations with more resources are already able to afford the expense of the most current advances, but they may still choose for the conventional if they need it. Businesses can be categorized according to their capitalization.This kind of geography is well-liked in small businesses since it is simple to use and understand. This also only requires a small number of connections to connect the PCs, and it's not difficult to scale up. Network traffic may obstruct a transport since every PC in the company can transmit information at any time. Similarly, any connection between two connections may cause the electrical indication to break down. The transportation setup may be difficult to track down in this kind of terrain, and it might cause the whole company to stop functioning. In a star geography, if one of the PCs fails, it has no effect on the others, which contributes to its impressive display. The hub of a star network is a good place to look for network flaws, because if one PC fails, the whole company isn't affected. The replacement or removal of devices is simple. For small groups of workstations or larger networks with comparable workloads, the ring network provides excellent performance. Ring

networks, in comparison to other types of networks, can span longer distances and are also easily expandable. Because the tokens are data packets that are re-generated at each node, there is no signal loss in Ring topology, unlike a bus topology. There are many degrees of abstraction in the modeling process. The structural characteristics of a network are formed by a network topology model. Due to indication, dedicated instances of network equipment such as various kinds of routers, switches, and end system nodes are ignored. The second phase 'eliminates' and subsumes any things that are transparent to the layer under observation.

CONCLUSION

The choice of LAN Network geography would rely upon numerous contemplations upon the business circumstance yet the money saving advantage rule should consistently be applied when choosing things with respect to the business. These sorts of organizations may appear conventional however it can unquestionably be used for microenterprises, other business levels can likewise use it relying upon their carefulness. The modernization of innovation may not be that pertinent to all in light of the fact that numerous imperatives might be viewed as, for example, financial plans furthermore, capacity to adjust innovation. In general, the specialist proposes further investigation of your business circumstance previously choosing what geography to utilize. Yet, in the event that that your first endeavor may not be that successful, there is consistently one more opportunity to improve it. Prior to having a stable framework, it is common that we might be in an experimentation strategy first.

ABSTRACT

The use of plant-based natural colorants and some other bioactive natural extracts in textile coatings as antimicrobial textile finishes is gaining traction. Several plant-derived natural colors have potent antibacterial effects. As a result, coating cotton textiles with antimicrobial plant natural dyes and bioactive plant extracts is a new technique in the manufacture of medical cloths. According to current research, depending on the kind of components contained in the plant extract, many plant extracts may be effective against several gram positive and gram negative bacteria. As a result, research on environmentally friendly antimicrobial compounds based on natural ingredients for use in textiles is gaining traction throughout the globe. This article presents a thorough overview of natural product-based bioactive agents for antimicrobial finishing of textile substrates, including chitosan, natural dyes, neem extract, and other herbal items. The mechanism of antibacterial activity of several types of active components identified in extracts of natural products has been described. The goal of this article is to provide the most up-to-date scientific information on the extraction and use of natural colorants in textile processing. The advantages and disadvantages of using natural colorants on textiles, as well as various techniques of extracting natural colorants, have all been addressed.

KEYWORDS:*Antimicrobial, Dyes, Fabrics, Natural, Plant.*

INTRODUCTION

Antimicrobial fabrics with enhanced functionality are used in a wide range of goods, including health and hygiene products, particularly clothing worn near to the body, and therapeutic diagnosis including infection control and barrier materials. A variety of textile products depends

on synthetic antimicrobial agents such as triclosan, metal and their salts, organometallics, phenols, quaternary ammonium compounds, and others have been developed especially in recent decades, with the rise in the amount antimicrobial fibre technologies and the growing awareness about cleaner surroundings and health promotion. Synthetic antimicrobial compounds are efficient against a wide variety of bacteria and have a long-lasting impact on textiles, but they have drawbacks in terms of side effects, nontarget microorganism activity, and water contamination. As a result, there is still a high need for antimicrobial textiles based on environmentally friendly agents that not only assist to minimize the negative effects of microbial development on textile materials, but also meet the statutory criteria set by regulatory authorities[1].

Natural ingredients such as chitosan as well as organic dyes have been extensively documented for antibacterial finishing of textile fabrics. Aloe Vera, Tea Tree oil, Eucalyptus oil, Tulsi leaf extracts, and other natural herbal products may also be utilized for this purpose, since there is a wide supply of medicinal plants with active antibacterial components. Despite the fact that many natural ingredients are rich in antimicrobial agents, research into their application in textiles is sparse and poorly documented[2].

ACCOUNT OF HISTORY

Cotton fabrics were used widely for tentage, tarpaulins, and truck coverings during World War II, and these materials needed to be protected against microbial assault. This was especially problematic during the South Pacific battles, when most of the combat occurred in jungle-like circumstances. The US army Quartermaster Crops gathered and recorded data on fungus, yeast, and algae isolated from cloth in tropical and subtropical regions throughout the globe in the early 1940s.Cotton duck, webbing, and other military materials were strengthened and scented with a combination of chlorinated waxes, copper, and antimony salts.

The US Department of Agriculture's Southern Regional Research Laboratory, the Institute of Textile Technology (ITT), and some of the ITT's member mills worked together to chemically alter cotton to enhance its resistance to rotting and other characteristics via acetylation and cyanoethylation. Because of the relatively high cost and loss of fabric strength during processing, these treatments have had limited industrial adoption. Furthermore, man-made fibres such as nylon, acrylics, and polyester, which are naturally resistant to microbial degradation, have been more widely used to replace cotton in many industrial textiles[3].

Also discussed on antibacterial finishing of cotton and cotton-polyester mix fabrics utilizing the active components of neem seed extract, a natural product. The Indian subcontinent's plentiful neem tree provides a great source of therapeutic chemicals. It has high antimicrobial potential, and its major components, such as azadirachtin, salannin, and meliantriol, have been effectively integrated to the cellulose substrate, imparting a semi-durable antibacterial activity against both Gram-positive and Gram-negative bacteria.

Figure 1: Illustrate the diagram shows the antimicrobial finish for textile

Additional elements included in textiles, such as lubricants, antistats, natural auxiliaries (sizing and thickening), and dirt, offer sustenance for bacteria. Furthermore, dirt, dust, and sweat solutes may serve as nutrition sources for bacteria. Because of their high hydrophobicity, synthetic fibres are more resistant to the development of germs than natural fibres. Under certain circumstances, the carbohydrates in cotton and the proteins in keratinous fibres may serve as a source of nutrition for bacteria. Wool is more susceptible to bacterial assault than cotton, while cotton is more susceptible to fungal attack (Schindler and Hauser, 2004). As illustrated in Figure 1, the development of microbes on textiles causes unpleasant odors, fabric discoloration, and a decrease in fabric strength and other beneficial characteristics. For these reasons, limiting the development of microbes on textiles during storage and usage is much desired. Antimicrobial treatments may be applied to the textiles to reduce or eliminate the negative effects. Consumer attitudes toward cleanliness and an active lifestyle have recently resulted in a strong demand for antimicrobial-treated clothing fabrics, prompting extensive research and development[4].

Microbes

Microbes are microscopic organisms that could be seen with the naked eye. Microorganisms such as bacteria, fungus, algae, and viruses are examples. Warmth and moisture are ideal conditions for bacterial development. Microbes are the smallest organisms that are invisible to the naked eye. Bacteria, fungus, algae, and viruses are among the microbes found there. Bacteria are unicellular creatures that develop quickly in warm, wet environments. The bacterium family is further divided into Gram positive, Gram negative (E-Coli), spore carrying, and non-spore bearing subgroups. By consuming the cellulose content in the textile material, microbes degrade the performance characteristics and quality of the textiles, causing discoloration. Fungi are shown to be active at a pH of 6.5. Algae is a kind of microbe that develops in the presence of water and sunlight, causing deeper stains on textiles. The dust particles in the environment may adhere to the human skin, causing allergic responses as well as respiratory problems[5].

Textiles with antimicrobial properties

Clariant's Actigard finishes are used in carpets to fight bacteria, house dust mites, and mould fungus. Avecia's Purista-branded goods were treated with Reputex 20, a poly biguanide hydrochloride (PHMB)-based antibacterial having a wide range of antimicrobial action and minimal mammalian toxicity. PHMB is best for cotton and cellulosic fabrics, although it may

also be used on cotton-polyester and nylon mixes. In addition to the aforementioned antimicrobial chemicals, Table 1 lists synthetic fibres having built-in antibacterial characteristics.

Process of Antimicrobial Finishing

Antimicrobial finishing gives the capacity to prevent the development or reproduction of at least some kinds of microorganisms or to kill) at least some types of microorganisms to the textile substrate. As a result, an antimicrobial finish should be capable of killing bacteria by breaching cell walls or altering cell membrane permeability, impeding microbe protein synthesis, and inhibiting enzyme production required for microbe feeding. Several well-known antimicrobials, such as silver, quaternary ammonium compounds, N-Halamines, triclosan, and polyhexamethylenebiguanide, are almost biocides[6].

TABLE 1: THE FIBRES DERIVED FROM SYNTHETIC WITH BUILT-IN ANTIMICROBIAL PROPERTIES

Polymer	Company	Brand
Polyester	Trevira	Trevira Bioactive
	Montefibre	Terital SANIWEAR
	Brilen	Bacterbril
Polyacryl	Accordis	Amicor
	Sterling	Biofresh
Polyamide	Kaneba	Livefresh
	R-STAT	R-STAT
	Nylstar	Meryl Skinlife
Polypropylene	Asota	Asota AM Sanitary
Polyvinyl chloride	Rhovyl	Rhovyl's asAantibacterial
Regenerated cellulose	Zimmer AG	Sea Cell Activated

Mechanism of Finishing

Based on the antimicrobial function of the specific finish on the textile, three finishing processes may be identified. Control-release, regeneration, and barrier-block are examples of these systems. The first two finishing mechanisms aren't working properly. The longevity of the control release mechanism after washing and the leaching of antimicrobial agents from fabric that may come into touch with the wearer's skin are also issues. These chemicals have the ability to irritate normal skin, resulting in severe skin irritation and allergy problems. These issues may arise if the fabric is treated with a regenerate mechanism, since these agents need chlorine bleach to activate their antimicrobial effects after washing. Chlorine bleach is not only damaging to cotton fabrics, but also to human skin. The barrier-block technique does not have the drawbacks that the other two approaches have. These compounds are attached to the surface of the fabric and do not leak, killing germs that come into touch with it[7].

The textiles get advantageous properties such as fire resistance, wrinkle resistance, mildew resistance, and so on throughout the finishing process. This high-value-added cloth has resulted in a competitive consumer market. In recent years, there has been a rising awareness of the need of maintaining a healthy and sanitary environment. The illness is usually transmitted from person to person via contact with the infected individual's hands, clothing, and other body parts. Antimicrobial textiles are widely used in surgical gowns, undergarments, and infant apparel, among other applications.

Traditional clothes and household textiles are increasingly being treated with antibacterial finishes. To regulate their impact, antimicrobial drugs kill or prevent pathogen development. Because of the presence of carbohydrate in textiles, natural fibres such as cotton are readily attacked by microorganisms. Antimicrobial finished fibres are used in a broad range of sports

apparel applications. Intimate appealing, footwear, medical textiles, furniture, automotive textiles, and so forth. The presence of microbes in textiles results in an unpleasant odour, discoloration, and health issues. Microbial infections may be harmful to the skin, therefore any clothing that is worn close to it should have an antibacterial coating.

Types of antimicrobial agents

Antimicrobial agents are of two types

- Leaching
- Non-leaching

For the antibacterial finish, synthetic antimicrobial compounds which including quaternary ammonium compound, triclosan, and others are employed. These synthetic antimicrobial medicines, on the other hand, are long-lasting yet have many adverse effects. Synthetic antimicrobial drugs are now prohibited, according to the World Health Organization. According to US and European regulations, there is a growing need for eco-friendly antimicrobial fabrics that utilize natural antimicrobial agents like chitosan that do not damage the user. A range of chemical agents are available that may impart substantial impact in textile fibres to prevent the development of microorganism. The subsequent sections go over the many kinds of antibacterial chemical agents:

Organic Antimicrobial Agents

Organic antimicrobial agents such as quaternary ammonium compounds (QACs), N-Halamines, Polyhexamethylene Biguanide; triclosan; silicon-based quaternary agent; iodohors, phenols and thiophenols, heterocyclics, inorganic salts, nitro compound, urea, amines and formaldehyde derivatives, heterocyclics, inorganic salts,

Antimicrobial activity of QACs was evaluated on protein basis wool, cellulose base cotton, synthetic base polyamides, and polyester, with MIC values ranging from 10-100mg/l, demonstrating excellent repeatability and washing durability. These forms kill the bacteria by changing cell membrane permeability, impeding the synthesis of proteins of germs, inhibiting enzyme production required for microbes' sustenance. Through a pad-drycure procedure followed by exposure to chlorine bleach, the N-halamine chemical is utilized to create antimicrobial cotton fabric. The chlorinated sample has antibacterial properties against both Gram +ve and Gram –ve microorganisms. It was discovered that after 15 days of storage, 85 percent of the chlorine in chlorinated textiles could be recharged, indicating that N-halamine compounds had excellent biocidal effectiveness for healthcare textiles. Triclosan, an organic antibacterial agent, has been studied for its antimicrobial properties in polyester, nylon, regenerated cellulose, and acrylic fibers, with MIC values of less than 10ppm against bacteria. Triclosan has good durability after use/washing and it inhibits microbiological growth by blocking lipid production. Poly-hexamethylene biguinide is the most widely used organic agent in the healthcare, pharmaceutical, and food industries (PHMB). It works against both kinds of bacteria as well as yeasts and fungus. PHMB is somewhat poisonous, and there have been less reports of skin infections. It was used to prevent microbiological development in a range of goods, including underwear and towel fabric, and it had an excellent washing durability.

In Organic Antimicrobial Agents

For antibacterial effects on textiles, inorganic finishing agents such as metal oxides, copper and zinc, titanium, magnesium, silver, and gold were used. With MIC values of 0.05-0.1 mg/l against gram negative bacteria, E.coli, these agents showed excellent durability for cellulose, protein, regenerated, and synthetic materials. Sliver is a widely used inorganic antibacterial chemical that kills bacteria by inhibiting and disengaging intracellular proteins. Silver, on the other hand, is a

minor toxicant that releases slowly and may cause cloth to wear out. Zeolites of the chabazite type with the best morphology and lowest silicon to aluminum ratio (Si/Al)solution were modified with different combinations of silver, copper, and zinc ions to make single, binary, and ternary metal cation-modified zeolites. Silver-based zeolites had better antimicrobial activity than the others and had good/suitable mechanical properties. Furthermore, the results verified its capacity to control the spread of hazardous microorganisms in food processing and storage environments. As a result, these cutting-edge antimicrobial materials have uses in hygiene surfaces, kitchen accessories, and packaging.

Antimicrobial Agents' Effects on Human Health and the Environment

Antimicrobial textiles' environmental effect is dependent on a number of variables, including substrate material, antimicrobial chemical manufacturing, textile treatment production, and ultimately disposal mode and is a major source of concern. Antimicrobial agent production and disposal have a substantial impact on environmental factors, from substrate selection through ultimate disposal. They may end up in the aquatic body if the discarded antibiotic is not eliminated from the effluent. One approach is to remove synthetic compounds via waste water treatment for triclosan. The breakdown of quaternary ammonium compounds (QACs), which are classified as "hard antimicrobial agents," is usually regarded unsatisfactory. Aerobic condition treatment is a suitable choice for triclosan elimination since it degrades in 41 minutes and has a half-life of approximately 10 days in water. Drug resistance occurs in microorganisms as a result of changes in their genetic composition as a result of continuous antimicrobial exposure. Resistant strains may reproduce and spread because they are not destroyed by standard antibiotics. Antimicrobial agent safety is receiving a lot of attention. Natural antimicrobial compounds having a broad antibacterial range and a low environmental impact are in great demand. When evaluating the bio effectiveness of antimicrobial agents on textiles, the mechanism of action, type of active agent, concentration on textile, skin sensitivity, and irritation level are the most important variables to consider.

LITERATURE REVIEW

Antimicrobial fabrics have acquired a lot of attention and acceptance in the market and in everyday life during the past two decades, according to A.RESHMA et al. Textile manufacturers continue to experiment with new techniques in order to improve the quality of their goods and please their consumers. Increased industrial competitiveness has resulted in the development of several synthetic antibacterial agents. Despite their widespread usage, synthetic agents represent a danger to both people and the environment. Several environmental organizations have enacted regulations regarding the use of synthetic substances in light of these grave concerns. Natural antimicrobial treatments, on the other hand, are gaining popularity since they have less side effects on people and are environmentally benign. Antimicrobial qualities may be found in plants such as basil, neem, turmeric, clove oil, chitosan, sercin, onion, aloevera, and pomegranate. This review article discusses the many natural antimicrobial sources, their impact on the general population, and the potential for utilizing these agents in textiles to impart antimicrobial characteristics and create various products[8].

Brigita Tomsic investigated antimicrobial agents currently used in fabrics, such as quaternary ammonium compounds, Nhalamines, chitosan, polybiguanides, and triclosan, noble metal and metal oxide nanoparticles, and bioactive plant-based products, as well as nanoparticles of noble metals and metal oxides. Antimicrobial agents are classified as biocides and biostats, leaching and binding antimicrobials, controlled-release and barrier-forming agents, and agents with poor and excellent washing resistance based on their antimicrobial activity, toxicity, durability, and ecological acceptability. Due to the requirement for environmentally acceptable antimicrobial finishing, great deal of research has developed for the synthesis of antimicrobial agents that

replace the leaking antimicrobials with bound antimicrobials. Polymerizable quaternary ammonium salts of acrylate groups, alkyltrialkoxysilanes with incorporated quaternary ammonium clusters, reactive cationic dyes, appropriate crosslinking agents, complexes with cyclodextrines, and encapsulated nanoparticle agents embedded into polymer matrices of various compositions have all been used to make the latter[9].

M Joshi et al. conducted research on antimicrobial completing of textiles utilizing natural materials such as chitosan, natural dyes, and other herbal items. Also discussed is research on antibacterial finishing of cotton fabric utilizing active components from neem seed extract, a natural herbal product. The neem tree, which may be found in abundance across the Indian subcontinent, is a rich source of therapeutic chemicals. The antibacterial properties of neem seed extract have been effectively incorporated into a cellulosic substrate, providing a semi-durable antibacterial activity against Gram-positive and Gram-negative bacteria[10].

DISCUSSION

After the oil sector, the textile industry is the second biggest polluter. As the world moves toward sustainability, it is becoming more essential for the textile sector to abandon harmful chemicals in favor of natural resources. Many nations across the globe have tightened regulations on the manufacturing of textile goods, forcing producers to seek out safer alternatives. There have been obvious advancements in natural dye/antimicrobial extraction techniques, such as the creation of ultrasonic, enzyme aided ultrasonic, and microwave assisted extraction methods, which have shown to be more efficient than traditional approaches. According to a review of relevant publications, most natural colors have intrinsic antibacterial characteristics and therefore may have significant therapeutic efficacy. While natural dyes are more environmentally friendly than synthetic dyes, the amount of mordents used for greater fastness is often higher than the official allowed concentration, posing environmental concerns. Metallic mordents are gradually being phased out in favor of cleaner/greener alternatives also including natural tannins from plants as bio-mordents, or cleaner technologies such as plasma, microwave, ultrasonic, and others that provide greater yields than traditional techniques. More scientific effort in the area is required to accomplish this.

CONCLUSION

Antimicrobial finishing agents come in a wide range of options. However, there may be restrictions in order to meet acceptable performance, environmental characteristics, and economic criteria. The majority of inorganic antimicrobial compounds are toxic, have a high propensity for environmental degradation, block a narrow spectrum of microorganisms, and have poor laundering durability; however, organic antimicrobial agents have fewer side effects. Plant-based nano-particle antimicrobial agents are increasingly being utilized in a variety of sectors, owing to their superior features and pathogen protection when compared to commonly used biocides, and such value-added finishes may offer sustainable healthcare applications in textiles. These dyes are derived from various plant components such as the bark, leaf, root, seed, fruit, and flower, which include coloring elements such as tannin, flavonoids, and quinonoids, among others. As a result, natural antibacterial compounds originating from plant sources will play a vital role in the future. This study has gone to great lengths to incorporate all relevant referenced articles on the use of natural dyes/antimicrobials in green textile treatments. However, due to a lack of resources and the large number of publications in this area, the comprehensiveness of this study may have been compromised. Please accept our deepest apologies to any and all writers whose work was not included in this evaluation.

ABSTRACT

If all cooling and heating systems in OECD nations were powered by solar energy, solar energy could theoretically provide 10% of total energy consumption. This study examines cooling systems for residential and utility buildings in both South and North Europe, and analyzes the most viable options when solar energy is utilized to meet these buildings' cooling demands when heat rejection temperatures are high. The solar electric and solar thermal pathways are also being explored. Both concentrating and non-concentrating thermal methods are discussed. The conclusion is that vapor compression cycles in conjunction with PV collectors now provide the most cost-effective options. Vapor compression cycles powered by energy supplied by parabolic dish collectors and Stirling engines are the second best choice. The double-effect absorption cycle with concentrated trough collectors is the best thermally driven option, followed by desiccant systems with flat-plate solar collectors. Options for adsorption systems are considerably costlier.

KEYWORDS: *Refrigeration, Solar Energy, Solar Collector, Solar Cooling Compression System, Sorption System.*

1. INTRODUCTION

Our planet's primary source of energy is solar energy. The availability of energy in the terrestrial environment is shown by Hermann (2006). The majority of solar radiation that reaches the terrestrial environment is dispersed, with just a tiny portion transformed into solar energy (959 PJ year1, compared to 1,356,048,000 PJ year1 wasted only for surface heating). According to the International Energy Agency (IEA), global solar conversion in 2011 was 711 PJ (74%) thermal, 234 PJ (24%) PV, and 14 PJ (2%) concentrating solar power, for a total of 959 PJ year1. As a result, solar energy's potential is enormous. The distribution of energy uses in the residential sector of OECD member nations in 2011 is shown in Figure 1 (IEA, 2013). The 25,000 PJ total annual energy usage is a tiny percentage of the solar energy lost in surface heating. Space

heating accounted for almost half of the total (12,350 PJ), while space cooling accounted for just 6%. (1610 PJ). The "services" sector, which includes utility buildings, is not included in these figures, although it uses a significant amount of energy for heating and cooling (about 7000 PJ). This means that solar-driven refrigeration/heat pump cycles have the capacity to service approximately 10% of OECD nations' energy consumption (225,752 PJ). Although solar cooling is mostly utilized to remove cooling loads from applications, the same cycles that are used as heat pumps will have an advantage over using solar heat directly for heating. The identification of the demand side is the first stage in the assessment of solar cooling systems: which applications would be best serviced by solar cooling and how does the cooling demand change over time. We differentiate between residential air cooling, utility building air conditioning, and freezing applications in this research. The criteria for freezing applications are extremely precise, and they will not be addressed in this article [1][2][3].

Paul provided the utility building cooling load profile for Northern Europe (1995). The ratio of the peak cooling power needs of residential buildings in the Netherlands and Spain was used to calculate the peak cooling power demand for the utility building in Spain. During the same time period, the graphic also displays the highest solar radiation for the respective regions. The scale has been tweaked to emphasize the correlation between solar radiation availability and cooling load demand. The heat rejection temperatures on the process side are considered to be 10 K higher than the ambient temperatures. Solar cooling is a reasonable option since cooling demand rises in tandem with the intensity of solar radiation. Many initiatives for the development or demonstration of solar cooling technologies and solar cooling systems were undertaken. an absorber, ambient c condenser, cool cooling e evaporator, cool cooling el electricity g generator, heat driving heat pow mechanical power s, solar radiation, solar collector Standard test conditions (STC). Heating and cooling of the space cooking utensils utensThe initial goal of this article is to provide an overview of the state-of-the-art of the various methods available for solar-powered cooling. In the past, most review papers focused on solar thermal technologies, particularly sorption cooling (Lamp and Ziegler, 1998; Li and Sumathy, 2000; Grossman, 2002). Kim and Infante Ferreira (2008) provided a review that included solar electric, thermo mechanical, sorption, and other newly developing technologies in order to provide a wider perspective. This technique will be used here as well. Both technologies are considered by Lazzarin (2014). The second goal is to evaluate the capabilities of these various technologies in terms of providing competitive, long-term solutions. By comparing the starting prices of several alternative solar cooling pathways, the present commercial state of various sun cooling technologies will be assessed. Several of the most popular routes will be examined as alternatives in this study. Figure 3 depicts the technologies that were examined. Chan et al. (2010), Duan et al. (2012), and Santamouris and Kolokotsa recently evaluated passive solar cooling methods (2013). These methods include natural ventilation-based cooling as well as evaporative cooling.

Last but not least, evaporative cooling may be used both directly and indirectly. The topic of passive solar technology will not be discussed further.Photovoltaic panels and an electrical cooling device are the primary components of a solar electric cooling system. Solar cells are semiconductors, and their efficiency and cost vary greatly depending on the materials used and the manufacturing techniques used. Wafer-based crystalline silicon cells accounted for almost 90% of the PV industry in 2010 (Tyagi et al., 2013). In 2013, specifically for the Netherlands, these commercial cells had an average peak efficiency of 13%. Defines efficiency as the ratio of power production W (kW) to the product of solar panel surface area as (m2) and incoming radiation Ip (kW m2). The nominal efficiency is usually calculated using the Ip 14 1 kW m2 formula. Around 750 solar cooling systems were built globally in 2011, including installations with modest capacities (less than 20 kW) (IEA, 2012). Although each technology has its own set

of advantages and disadvantages, a high initial cost is a common issue. The necessary investments for converting solar energy into electrical or thermal energy to supply the various technologies were estimated in the preceding sections. An estimate of the investment costs of various cooling cycle methods, including installation expenses. It also includes values suggested in recent publications for comparison. Some systems need the use of an engine (Stirling or Rankine).

After that, a value of k V 1.7 kW1 shaft power was evaluated. the different solar cooling methods described in the preceding sections in terms of starting costs for residential applications in the Netherlands. The vapor compression cycle, powered by energy supplied by solar collectors, seems to be the most appealing option for Central European circumstances at the moment; the cost of these collectors has dropped dramatically. The second best alternative is a vapor compression cycle powered by energy supplied by parabolic dish collectors and Stirling engines, which have a comparable investment level. With a considerable difference, double-effect absorption cycles in conjunction with concentrating parabolic trough collectors and desiccant cooling in combination with flat plate collectors follow. Other alternatives need considerably more investment. .Figure 1 shows the Alternative Routes from Solar Energy into Cooling/Heating Effect Using Thermodynamic CyclesDespite the fact that many sun cooling technologies are deemed mature, solar air conditioning systems have a limited overall cooling capability.

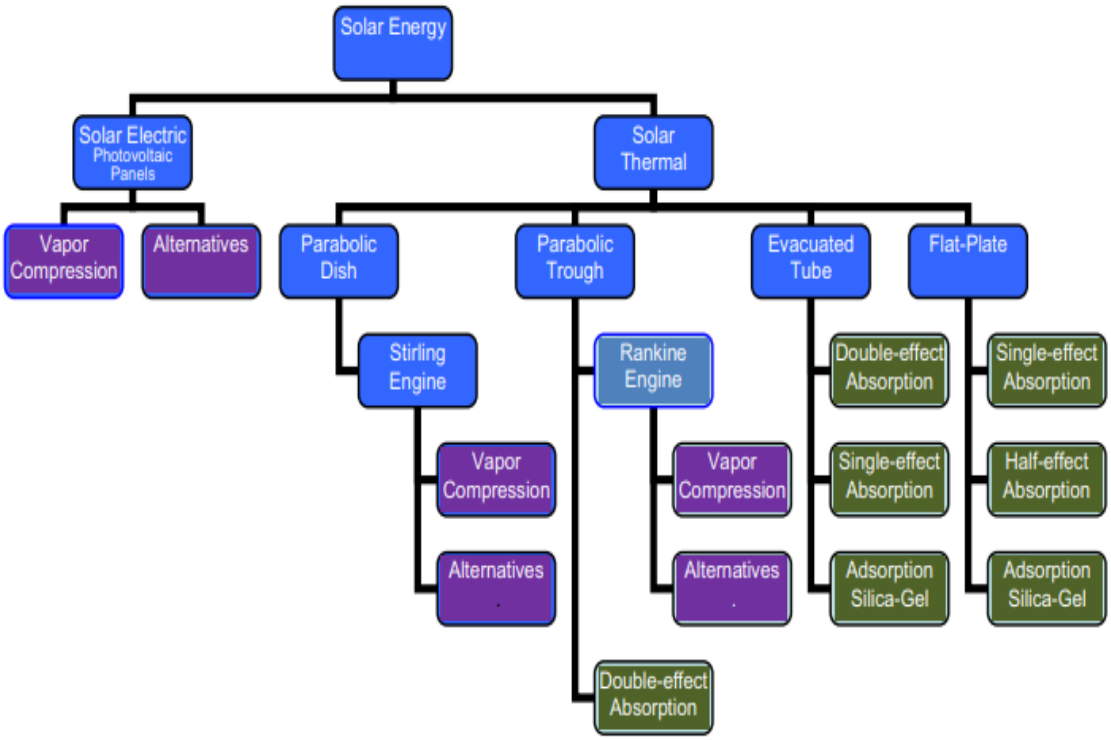

Figure 1: Alternative Routes from Solar Energy into Cooling/Heating Effect Using Thermodynamic Cycles.

2. DISCUSSION:

The inverter, connections, and dirt buildup on the surface of cells are all taken into account, and the average value is 0.86. Huld et al. have presented a technique for predicting Panel (which is expressed in C) (2010). For the climatic conditions in the Netherlands, this translates to an annual energy output of 106 kWh m2 and a peak power of 94 W m2. According to the IEA

(2013), solar PV capital costs are continuing to decrease, with large-scale systems costing V 1.1e2.6 Wp1 and small-scale systems at V 1.8e4.5 Wp1 in 2012. The cost of a solar PV panel varies greatly depending on the market. The average installed consumer price of a solar panel in the Netherlands in 2013 for small systems was V 250 per m2 (V 2.1 per Wp for a peak output of 117.5 W under 1 kW m2 of solar radiation). The DCeAC converter and electric net connection are included in this pricing. To account for variations in local markets, the average installed consumer price of a PV solar panel for small-scale projects is estimated to be in the range V 250e400 per m2 and in the range V 150e250 per m2 for large-scale projects. When coupled with a traditional vapor compression system, the greatest benefit of utilizing solar panels for cooling is the ease of installation and high overall efficiency In thermodynamics, COP (Coefficient of Performance) is an alternate word for efficiency. The COP of a Carnot (ideal) cycle operating in the same high and low temperature reservoirs limits the efficiency of vapor compression cycles. The efficiency of the second rule, a, may therefore be utilized to approximate the actual COP of the cycle: The efficiency of the second law will be determined by operating circumstances and component design [4]. For vapor compression cycles, anis set to 0.50 for calculation reasons. This benefit can be readily achieved in real-world systems without requiring significant expenditures. Solar power systems will always require some kind of energy storage and/or backup. Batteries may be used in solar electric systems, or they can be electric-net linked, allowing energy to be imported or exported from the system. The use of DC compressors provides for easy rotational speed adjustment and therefore efficient part load operation. Solar photovoltaic panels have become very affordable in recent years, making them highly competitive in contrast to other solar cooling methods. Table 3 summarizes the costs for the applications considered when the above-mentioned panel costs are combined with a solar photovoltaic panel with a 13 percent peak efficiency and a vapor compression air conditioner operating at a heat rejection temperature of 40 C (COP 14 3.9) or 50 C (COP 14 2.9) in the Netherlands and Central Spain, respectively.

A pinnacle Solar Power Electricity generated by the sun Photovoltaic Panels is solar panels that convert sunlight into electricity. shows the usual cooling load profile of residential structures in central Spain and the Netherlands (left) under peak circumstances, as well as the accompanying solar radiation (right)[5]. This load has been divided by 100 to correspond to the same scale. The electric power requirements for the Netherlands and Central Spain, respectively, are 0.77 kW and 1.38 kW for residential applications and 64.1 kW and 114.8 kW for office building uses, based on cooling COPs under peak load circumstances and peak load values The matching area and collector investment levels. Solar thermal cooling is number three. Solar thermal systems generate cooling by using solar heat rather than solar energy. The solar concentrating technologies are shown on the left hand side of the solar thermal conversion technologies in Fig. 3. The development of concentrated solar power (CSP) has not been as rapid as that of solar PV. Their solar energy contribution is less than 2%. These systems concentrate solar energy, allowing for very high working fluid temperatures.The schematics of parabolic dish collectors (point-concentrating; working fluid temperatures up to 750 C) (line-concentrating; working fluid temperatures up to 400 °C). In contrast to fixed inclination non-concentrating thermal collectors, both kinds utilize sun tracking systems to achieve high radiation levels for a longer length of time [6]

2.1. Application:

The reduction in irradiance is a significant consequence of solar thermal collector performance. The irradiance cut is the irradiance at which a collector begins to produce heat at the specified temperature level. Van Leeuwen (2010) calculated the heat production of collectors for three distinct heat delivery temperature levels using the average solar irradiation for a particular site in South Spain in conjunction with the associated ambient temperatures. Flat plate collectors

generate more heat on a daily basis than evacuated tube collectors. However, the difference between low and high heat delivery temperatures is only around 25%, whereas the difference between high and low temperature variations is more than 60%.Because flat-plate collectors are about half the price of evacuated tube collectors, the heat produced by flat-plate collectors is always less expensive (for the specific location considered).A heat engine transforms solar heat to mechanical effort, which powers a mechanical compressor in a vapor compression cooling machine in a solar thermo-mechanical cooling system. Figure 8 depicts a schematic design of such a cooling system (Kim and Infante Ferreira, 2008). A solar collector absorbs solar radiation Qs from the sun and provides Qg to a heat engine at temperature TH, as shown in the diagram. The thermal efficiency of a solar thermal collector, hsolheat, is defined as the ratio of supply heat Qg to radiation Qs. At temperature TM, a heat engine generates mechanical power W and rejects heat Qa to the environment. The power generated per heat inputQg, Eq, is defined as the engine efficiency, hheatpow. The cooling cycle's compressor is driven by the mechanical power W to remove heat Qe from the application at temperature TC. At the temperature TM, waste heat Qc, which is equal to the sum of Qe and W, is rejected to the ambient. The cooling cycle's efficiency is the same. Figure 2 shows e Schematic diagrams of non-concentrating solar collectors, Kim and Infante Ferreira (2008): flat-plate collector (left) and evacuated tube collector (right) [7].

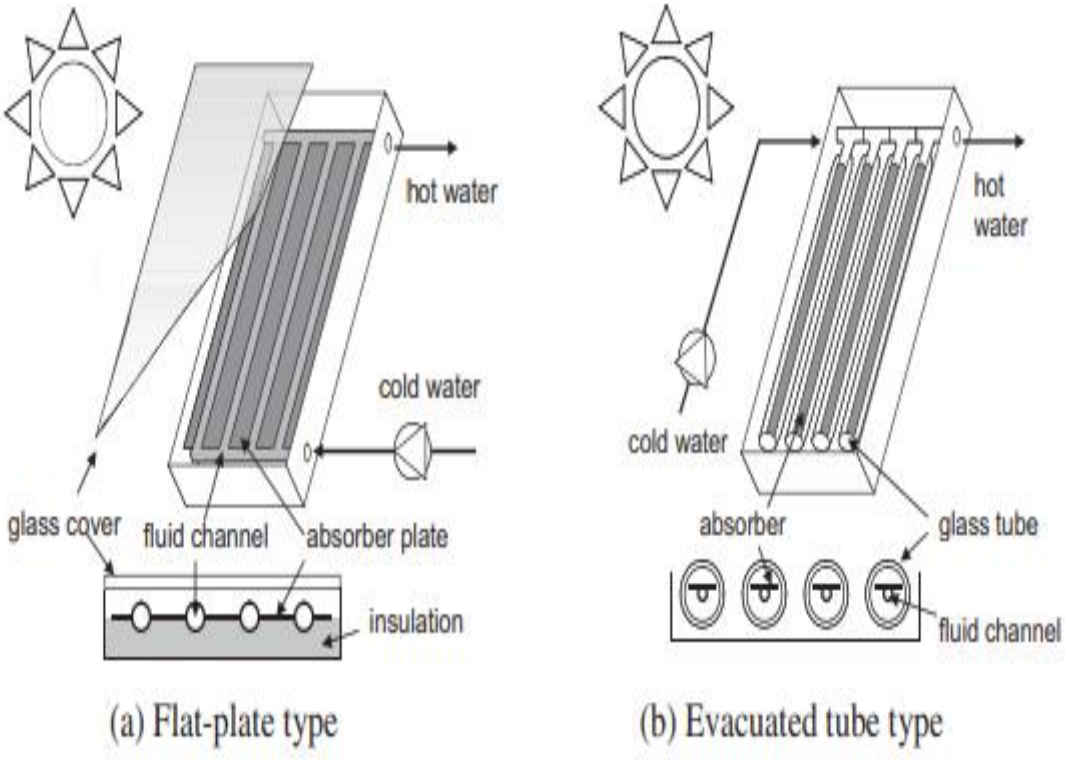

Figure 2: e Schematic diagrams of non-concentrating solar collectors, Kim and Infante Ferreira (2008): flat-plate collector (left) and evacuated tube collector (right).

2.2. Advantage:

The reduction in irradiance is a significant consequence of solar thermal collector performance. The irradiance cut is the irradiance at which a collector begins to produce heat at the specified temperature level. Van Leeuwen (2010) calculated the heat production of collectors for three distinct heat delivery temperature levels using the average solar irradiation for a particular site in South Spain in conjunction with the associated ambient temperatures. Generate more heat on a daily basis than evacuated tube collectors. However, the difference between low and high heat

delivery temperatures is only around 25%, whereas the difference between high and low temperature variations is more than 60%.Because flat-plate collectors are about half the price of evacuated tube collectors, the heat produced by flat-plate collectors is always less expensive (for the specific location considered).A heat engine transforms solar heat to mechanical effort, which powers a mechanical compressor in a vapor compression cooling machine in a solar thermo-mechanical cooling system. Figure 8 depicts a schematic design of such a cooling system (Kim and Infante Ferreira, 2008)[8] A solar collector absorbs solar radiation Qs from the sun and provides Qg to a heat engine at temperature TH, as shown in the diagram. The thermal efficiency of a solar thermal collector, hsolheat, is defined as the ratio of supply heat Qg to radiation Qs.

2.3. Working:

For the most part, absorption cooling has been used. Sun heating and cooling It just needs a little amount of electricity or none at all, and it may be used in a variety of ways. The physical dimensions of an absorption device have the same capacity. Due to the fact that adsorption machines are smaller, due to the absorbent's high heat transfer coefficient. Besides, the fluidity of the absorbent allows for additional freedom in designing a machine that is more compact and/or efficient. Kim and I are a couple. Infante Ferreira (2008) presents a summary of a vast number of studies research into sunlight absorption cooling Cooling by the sunindicates that the heat rejection temperatures are quite high. Similarlyin comparison to the vapor compression cycle's method, an absorption cooling machine's efficiency may be anticipated. By assuming a constant temperature, heat cools as COPCarnot.a number for the efficiency of the second law, using previously published performance data (Kim and Infante Ferreira, 2005), A circulation ratio (strong mass flow) should be used whenever feasible has been calculated by dividing the answer by the mass flow of refrigerant. Considered. H2OeLiBr has a single-effect and a double-effect. At heat rejection temperatures, cooling cycles are unable to function. Due to the crystallization limit at low water concentrations, the temperature must be kept below 50°C. Temperatures of 40 degrees Celsius need a bigger heat rejection system.Ratio of circulation taking the same operational conditions into account solar electric cooling devices that focus the sun's energy. The locality as a result of the electric power needs of the many applications, as well as collector efficiency The Only collectors are concerned about investing. Area that is required The most competitive is NH3eH2O.via the invention of solar-powered air conditioning pathway of adsorption Zeolite, silica gel, and activated carbon are examples of adsorbents. Carbon and alumina are physical adsorbents with high adsorption capacity.Permeable structures with surface-to-volume ratios of at least Hundreds of refrigerant traps that can selectively capture and hold refrigerants. They can be renewed if they get saturated. Getting warmed up when both an adsorbent and a refrigerant are present, the adsorbent would maintain pressure in the same vessel by adsorbing the evaporating refrigerant. The procedure is as follows: since the adsorbent must be replenished on a regular basis after it has reached saturation. As a result, several adsorbent beds are used. For continuous functioning, are needed. Adsorption chillers have cooling power densities that are very high. Are much lower than those for absorption chillers. Adsorption in big solar cooling systems, technology may be competitive. Its poor power density isn't an issue here. For small- or medium-sized businesses, It tends to be too large for medium-sized solar cooling systems As well as being costly [9].

3. CONCLUSION

There are many methods for converting solar energy into a cooling effect. This paper provides an overview of the most promising choices for particular applications in Central Spain and the Netherlands, as well as a ranking of the options based on the necessary investments. This investment level is based on the performance of the various alternative systems as stated. The

best choices seem to be vapor compression cycles combined with PV collectors. Vapor compression cycles powered by energy supplied by parabolic dish collectors and Stirling engines are the second best choice. The double-effect absorption cycle with concentrated trough collectors is the best thermally driven option, followed by desiccant systems with flat-plate solar collectors. Options for adsorption systems are considerably costlier.Again, the most appealing option for this application is the electricity is used to power the vapor compression cycle. Collectors of photovoltaic energy The cycle of vapor compression is fueled bestirring and parabolic dish collectors provide energy. The second best choice is engines. The twofold effect H_2OeLiBr absorption cycle cannot be used under these operating circumstances. because it would approach the crystallization line limit if it were to operate certain circumstances as a result, the second-best option is the Combining a single effect absorption cycle with a parabolic curve collecting in a trough Desiccant cooling is now used in conjunction with Flat-plate collectors are carefully following. The amount of money invested by theThe cost of other options is considerably greater. Alternative doubleeffect cycles, which are not constrained by crystallization line constraints, are anticipated to bring these cycles to fruition. A comparable stance to the one they hold for Central Europe because higher capacity may result in varying ratios between the two, investment in solar collectors and cooling systems the level of the various options The same seems to be true for industrial applications. The same rating system applies to residential applicants. PV has been around since Solar panels for large-scale projects are less expensive; nevertheless, solar panels for industrial use are more expensive.vapor compression cycles powered by energy supplied by solar collectors are unquestionably the best option for large-scale applications [10]

ABSTRACT

Urban Areas, Home Automation, Online, World Wide Web, Connectivity, Internet-of-Battlefield-Things, and other civilian and military applications of the Internet-of-Things are becoming more common. In this study, we review papers published in English since January 2016 that offer IoT security solutions. We offer a number of findings, including the paucity of publicly accessible IoT datasets for researchers and practitioners to utilize. Given the potentially sensitive nature of IoT information, a standard for exchanging IoT datasets across academic and practitioner groups, as well as other relevant stakeholders, is required.These devices will produce large or fast/real-time data streams, depending on the extent of the application. Applying analytics to such digital data to find new information, anticipate future insights, and perform control choices is a critical step that distinguishes IoT as a viable business model and a technology that improves quality of life. The potential for blockchains in enabling safe IoT dataset sharing (e.g., utilizing blockchain to guarantee the integrity of shared datasets) and protecting IoT systems is then discussed, followed by two hypothetical blockchain-based methods. The article is then concluded with nine possible research topics.

KEYWORDS:*Application Layer, Iot, Perception Layer, Security, Transport Layer.*

1. INTRODUCTION

The Internet of Things (IoT) goal is to use a broad variety of sophisticated technologies to convert conventional things into smart objects, ranging from embedded devices and electronic technology to Http protocol, data analytics, and so on. The potential economic effect of the Internet of Things is anticipated to open up a slew of new business possibilities and drive the development of IoT-based services. According to a study by McKinsey on the worldwide economic effect of IoT, the yearly economic impact of IoT in 2025 will be between $2.7 and $6.2 trillion. Healthcare takes up the majority of the market, accounting for 41%, followed by

industrial and energy, which account for 33% and 7% of the IoT market, accordingly. Transport, agricultural, public development, security, and retail each account for approximately 15% of the overall IoT market. These projections indicate that IoT services, their produced data, and, as a result, their associated market, will expand at a huge and sharp pace in the next years[1].

Because portions of many professions may be "ideal for ML applications," machine learning (ML) will have an impact on employment and the workforce. This will boost demand machine learning solutions, as well as the tasks, platforms, and expertise required to create them. In McKinsey's study, the economic effect of machine learning is described as "the use of computers to do activities that require sophisticated analyses, nuanced judgements, and creative problem solving." Advances in machine learning methods, such as deep learning and neural networks, are the primary facilitators of knowledge job automation, according to the study. Organic user interfaces, such as voice and gesture recognition, are additional enablers that are gaining traction thanks to machine learning. By 2025, the projected annual economic effect of knowledge job automation may be between $5.2 trillion and $6.7 trillion. The figure depicts the breakdown of this estimate by occupation. In comparison to the economic effect of IoT, this estimate emphasizes the importance of extracting value from data and the prospective implications of machine learning on the economic position of people and communities. Individuals and nations alike are affected by these economic effects, as people must adapt to new ways of generating money that are appropriate for them in order to retain their desired level of life[2]–[5].

Many IoT applications have emerged in recent years in many vertical areas, such as health, transportation, home devices, smart city, agriculture, education, and so on. An intelligent learning mechanism for prediction (i.e., regression, classifying, and clusters), data mining and pattern recognition, or data analytics in general, is a key component of most of these applications. Figure 1 shows the IoT data generation at different levels and deep learning models to address their knowledge abstraction[6].

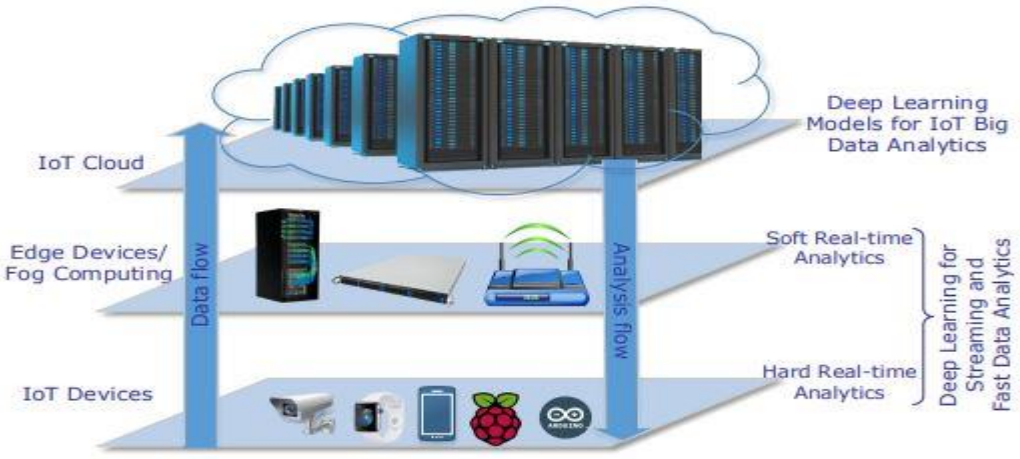

Figure 1: The above figure shows the IoT data generation at different levels and deep learning models to address their knowledge abstraction.

Deep Learning (DL) is one of the numerous machine-learning techniques that has been actively used in various IoT applications in recent years. The top three key technology trends for 2017 were revealed at Gartner Symposium/ITxpo 2016, and these two technologies (i.e., DL and IoT) are among them. Traditional machine learning methods do not meet the increasing analytic requirements of IoT systems, which is why DL has received so much attention. Instead, depending on the hierarchy of IoT data production and administration, IoT systems need various contemporary data analytic techniques and artificial intelligence (AI) technologies. The growing

popularity in the Internet of Things (IoT) and its derivative big data need a thorough understanding of its definitions, building blocks, potentials, and difficulties by stakeholders. There is a two-way connection between IoT and big data. On the one hand, the Internet of Things is a major source of big data, and on the other, it is a key target for big data analytics to enhance IoT operations and services. Furthermore, IoT big data analytics has proved to be beneficial to society. The Department of Park Management in Miami, for example, has stated that by identifying and repairing broken pipes, they have saved approximately one million dollars on their water costs[7]–[12].

IoT data is distinct from traditional big data. We need to investigate the characteristics of IoT data as well as how they vary from those of conventional big data to better understand the needs for IoT data analytics.

1.1 The following qualities may be found in IoT data:

1.1.1 Large-Scale Streaming Data:

For IoT applications, a plethora of data collecting devices are dispersed and deployed, generating streams of data on a continual basis. As a result, a massive amount of continuous data is generated.

1.1.2 Heterogeneity:

Because various IoT data collection devices collect different information, data heterogeneity occurs.

1.1.3 Time And Space Correlation:

In most IoT applications, sensor devices are connected to a particular place, thus each data item has a location and a time-stamp.

1.1.4 High-noise data:

Because IoT applications use small bits of data, many of these data may be susceptible to mistakes and noise during collection and transmission.

Although extracting hidden data and understanding from big data has the potential to improve our lives, it is not a simple or straightforward process. New technologies, methods, and infrastructures are required for such a complicated and difficult job that goes beyond the capability of conventional inference and learning techniques. Fortunately, recent advancements in both fast computing and sophisticated machine learning methods are paving the way for IoT-friendly big data analytics and information extraction.

Beyond big data analytics, IoT data necessitates a new kind of analytics, known as fast and fast data analytics, to support applications that need time-sensitive (i.e., real-time or close to real) operations.

Indeed, applications including such automated cars, fire prediction, and identification of driver/elderly position (and therefore awareness and/or health state) require rapid data processing and actions to accomplish their goals. Several academics have developed frameworks and methods for rapid streaming data processing that take use of cloud infrastructure and services. Fast analytics on smaller level platforms (i.e., at the system edge) and on the IoT devices themselves are required for the aforementioned IoT applications, among others. Autonomous vehicles, for example, must make quick judgments on driving activities including such lane or speed changes. Indeed, fast analytics of potentially multi-modal data streaming from the many sources, including multiple vehicle sensing (e.g., cameras, radars, LIDARs, vehicle speed, left/right signals, etc.), connections from other automobiles, and vehicle entities (e.g., traffic lights, traffic signs), should be used to support such decisions. In this instance, the delay in

sending data into the cloud server for processing and delivering the answer may result in traffic infractions or accidents. Detecting pedestrians by such machines would be a more dangerous situation. To avoid catastrophic accidents, accurate identification should be done in real time. To avoid needless and expensive connection delays, these situations indicate that rapid data analytics for IoT must be near to or at the data source.

1.2 Threats of IOT Model:

Three major layers may be used to properly define and explain a generic IoT system:

- Perception Layer
- Transport Layer
- Application Layer

It has its own set of technologies, each of which has its own set of problems and potential security flaws. Figure 2shows the IoT system model.

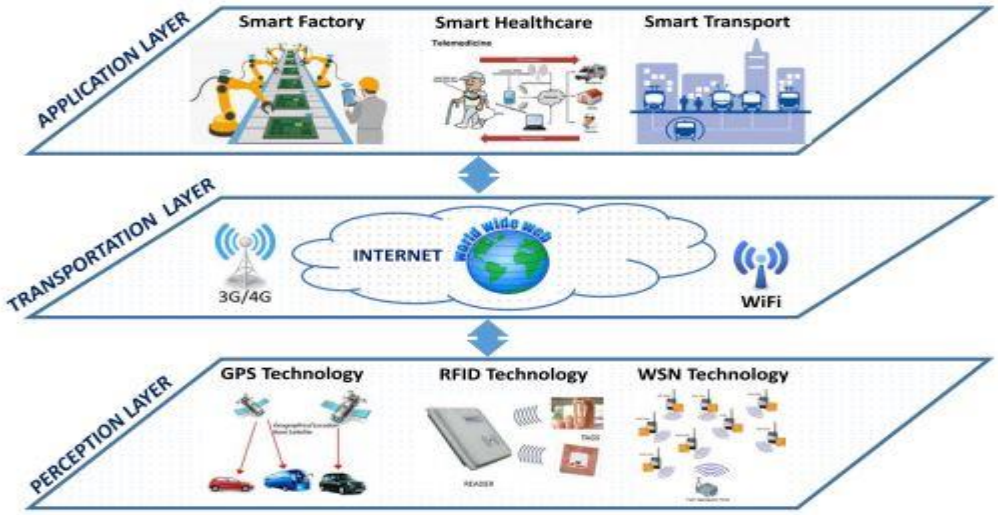

Figure 2: The above figure shows the IoT system model.

1.2.1 Perception Layer:

The first layer is for physical IoT sensors to enable data collecting and processing using several standard technologies including radio-frequency identification (RFID), wireless sensor networks (WSN), RFID sensor networks (RSN), and GPS. This layer contains sensors and actuators that conduct various measurements (temperature, acceleration, humidity, etc.) as well as functions like location querying. The major security risks posed by the perception layer are as follows, due to restricted node resources and a dispersed structured structure.

1.2.1.1 Physical Attack:

These attacks target the hardware components of the IoT system, and therefore need the attacker to be physically near to or within the IoT system to be successful. The following are some instances of such assaults.

- **Tampering Nodes:**

An attacker may harm a sensor node by physically changing the whole node or a portion of its hardware, or by electronically probing the nodes to obtain access to and change critical information like shared cryptographic keys or routing tables.

- **Malicious Code Injection:**

The attacker compromises a node by physically inserting malicious code into it, which allows him to get access to the IoT system.

1.2.1.2 False Identity:

Because authentication in a distributed environment is challenging, rogue nodes may employ a false identity to carry out hostile or collusion activities.

1.2.1.3 DoS (Distributed Denial of Service) Attacks:

Attackers take advantage of the nodes' limited processing power to render them unusable.

1.2.1.4 Attacks on the routing system:

During the data collecting and forwarding procedure, intermediate malicious nodes (for example, in a WSN) may alter the correct routing routes.

1.2.1.5 Cyber-Attacks on Data Transit:

Various attacks on data transmission confidentiality and integrity [e.g., sniffer and man-in-the-middle (MITM)];

1.2.2 Transport Layer:

The perception layer is primarily served by the transportation layer, which offers a ubiquitous access environment. This layer's goal is to send the collected data from the perception layer to any information processing system through existing communication networks utilized by both access networks (3G, WiFi, ad hoc networks, and so on) and core networks (Internet).

A short review of security problems in wireless networks, such as cellular networks, may be found in. The open and diverse design of an IP-based LTE network, according to this study, is resulting in a higher number of security risks than 3G networks.

The following are the major security risks at this level:

1.2.2.1 Attacks On The Routing System*:*

During the data collecting and forwarding procedure, intermediate malicious nodes (for example, in a WSN) may alter the correct routing routes.

1.2.2.2 Denial Of Service (Dos) Attacks:

The transportation layer is susceptible to attack because of the variety and complexity of the IoT network.

1.2.2.3 Cyber-Attacks On Data Transit:

Various assaults on data integrity and confidentiality during data transmission in access or core networks

1.2.3 Application Layer:

Customers request services, which are provided by the application layer. Customers that want temperature and air humidity readings, for example, may get these via the application layer. This layer is critical for the Internet of Things because it can offer high-quality smart services to satisfy consumers' requirements. Many different IoT environments (such as smart cities, smart healthcare, and smart factories) can be implemented at this level; additionally, an application support sublayer could be implemented throughout specific middleware and cloud computing platforms to support all types of business services and to realize intelligent computation and resource allocation.

The following are the major security risks inside this layer:

1.2.3.1 Data Breach:

Knowing the vulnerabilities of the service or program, the attacker may simply steal data (including data users, such as user passwords).

1.2.3.2 Denial-of-Service Attack:

Attackers may take down the application or service's availability.

1.2.3.3 Injection of Malicious Code:

Attackers may inject malicious code into software programs by exploiting known flaws.

2. DISCUSSION

The significance of security in the IoT is progressively increasing, in tandem with the fast growth of the IoT sector.Indeed; we have demonstrated that the IoT system architecture has many security concerns, including attacks that may exploit certain potential flaws. As a result, starting with the categorization of the many risks linked to each particular level of the community IoT system architecture, it is essential to properly implement trust security with in IoT world.The perception layer, according to this study, is the most susceptible level of the IoT system architecture owing to the activity in patients of IoT devices, their limited resources, and their technical variety. As a result, it is essential to begin working on the key problems at this level in the near future by developing lightweight security mechanisms that can adapt to diverse settings with resource-constrained devices.

3. CONCLUSION

The Internet of Things (IoT), a new concept that aims to improve the quality of life by linking different smart gadgets, technologies, and apps, is rapidly gaining traction in our contemporary lives. In general, the Internet of Things (IoT) would enable the automation of anything around us. This study provided an outline of the concept's foundation and applications. We have summarized several studies on IoT layered architectures and described security threats based mostly on layers that may affect IoT performance. The features and limits of communication technology have been described. We combed the literature for current techniques to safeguard IoT infrastructure and evaluated these security approaches in terms of how they handle IoT security concerns. We have also compiled a list of the current security techniques' limits and limitations.We also suggested a novel six-tiered layered architecture for securing IoT infrastructure.In addition, many open research problems related to IoT technology were addressed as potential future paths. These issues must be addressed and handled right now.

ABSTRACT

The article discusses the peculiarities and artistic skills of George Orwell's artistic style, his attitude to social reality, the problems of commonality and originality in his artistic reincarnation. Observing the peculiarities of the writer's distinctive colorful images and portraits, the character is sketched, and the skill of welding each impression to it with a strong stroke and great speed is analyzed. The concept of society, which is a very important and global problem for the development of society and fiction, as well as the dialectic of multi-layered imagery in the artistic interpretation of this topic are summarized in the example of English and Uzbek literature.

KEYWORDS: *Double Thinking, Dystopia, Dictatorial System, Social Content, Multi-Layered Metaphor, Artistic Psychology, Personality And Society, Artistic Mode, Socio-Moral Character, Reality Of Social Life, Philosophical Thinking, Personality Tragedy, Subconscious, Time And Space, Conflict.*

INTRODUCTION

The masterpieces, which are very popular in world literature, can be conditionally divided into two. The first is the works written in protest of Dostoevsky's "Demons", L. Tolstoy's "War and Peace", Stendhal's "Church of Parma", E. Hemingway's "Goodbye, weapon!" Solzhenitsyn's "Gulag archipelago", Igor Bunich's "Gold of the Party", ChingizAitmatov's "Straw Road", "Mountains are falling", O. Yakubov's "Address of Justice", Sh. The second type of works is the masterpieces of art, which are in essence against the existing systems, oppression, human freedom, the freedom of nations, in high art: Dante Alighieri's "Divine Comedy", A. Navoi's "Farhod and Shirin", "SaddiIskandariy", Goethe's Faust ",“ The Adventures of Don Quixote "by Miguel de Cervantes, J. Swift's "Gulliver's Travels" (J. Orwell's ideal favorite artist), M. Bulgakov's "Ityurak", "Seeds of Disaster", "Master and Margarita", F. Kafka's "Process",

A.Kamyu's "The Stranger", L.Andrev's "Judas Iscariot", A.Qodiri's "Last Days", "Scorpion from the Altar", Cholpon's "Night and Day", Fitrat's "Abulfayzkhan", "Resurrection", Ch. Aitmatov's works such as "Asrgatatigulik kun", "Qiyamat", A. Aripov's "Jannatgayol", "Ranjkom", O. Mukhtor's "Fu", "Aflotun", H. Dostmuhammad's "Jajman", N. Eshonqul's "Tobut". based on symbolism and social metaphor. It is a unique style that has a very long history in world literature, and is also unique to the work of the English writer George Orwell, whose works have become bestsellers. The works of MM Dost, which we have based on a comparative-typological study with the work of J. Orwell, are also based on symbols and metaphors, social allusions.

In order for a person to strive for freedom, independence, individual love, a person must first be able to rise to the highest stage of his development. For this, there must be the necessary social conditions, that is, the state must renounce violence and the use of primitive force, and focus on the development of science, the perfection of the individual. If such a perfect system is created, neither external nor internal forces can control it. One of the social functions of works of art is to promote this idea. One of the peculiarities of J. Orwell's style is that in it the sentences are short, often logically complete, in the form of a simple sentence, and the comments are clearly stated in the author's language. "Even in the name of our leader, there is a faceless overthrow of the facts," he said. The Ministry of Peace deals with war, the Ministry of Truth with lies, the Ministry of Love with torture, the Ministry of Welfare with famine. These contradictions are neither accidental nor hypocritical; it is a practice of double thinking"[1; 203]. It is clear from the quotation that the writer expresses his thoughts very closely, and it is difficult for the average reader to fully comprehend the sentences being uttered from one reading to the end. In order to digest meaningful ideas, the reader must be aware of socio-political life, society and history, as well as have the ability to think in a healthy and deep way.

The paradox of love and power is fully, deeply expressed in George Orwell's 1984 novel. As in any dystopia, the concepts of love and power are the same here: as opposed to the mutual love of the ruler and the citizens, they are seen as mutually exclusive.Because the demand of the party is only to love oneself, to completely forget everything else, to sacrifice oneself for the party.

That's why the relationship between power and people (especially Winston and Julia) is built on a love story scenario. Power seeks to assimilate the object of love, to fully subdue all its actions and to direct its thoughts to itself, to interest the object, to demonstrate various techniques and mechanisms: from simple encounter to sadistic violence, the essence of the dictatorial system is demonstrated. The party controls everything, even the couple's relationship.The situation escalates to the point where people are imprisoned and punished just like Parsons for their dreams [1; 221].

In 1984, a dispute between Winston and O'Brien revealed the government's intentions. "You're recovering. There is no flaw in your mind. Emotionally, you have not had a definite improvement. Tell me, Winston, just remember, don't lie, lie won't hide from me, you know that, tell me, how do you actually look at Big Brother?

"I hate him."

"You hate him." Good. Then it's time to take the last step for you. You must love Big Brother. Obedience to him is not enough; you must love him "[1; 267].

Winston tries to resist these claims as much as possible, but the horrific torture, the physical torment that eats away at the human mind, eventually breaks his spirit. He will be forced to sell the woman he loves, to betray her. At the same time, both sides - Winston and Julia - fall victim

to the love in their hearts, and the love duel ends with the “defeat” of the lover. The play details the relationship between Winston, Smith, and O’Brien, as well as images of women that fit into a well-known system of gender stereotypes. It should be noted that there are significant differences in the interpretation of the concept of love by the English and Uzbek writers, which can be explained by national identity.

MM DostYakhshibaev, who forgot himself as Oshno, could not understand the meaning of his life, was afraid of his own thoughts if he thought about it, spit on everything like Avvalbek, betaine, indecisive, who can say what like Olloyor? created the image of people who are accustomed to it as well, without will. This is what the communist ideology, the dictatorial system, has done to them. There is also a deep symbolic meaning when Ms. Muhsina mentions Oshna’s name with excitement and respect. He has become a slave to power, career, fame, and luxury. George Orwell predicts that future generations will be in such a predicament: "Winston, how does man establish his authority over others?"

Winston thought.

"By torturing him," he said.

- Absolutely right. By torturing him. Obedience alone is not enough. If a person does not suffer, how do you believe that he is doing your will, not his own? Power consists of suffering and humiliation. The power is to break the minds of the people and restore them in a way that is acceptable to you ”[1; 253].

Indeed, even 30 years ago, we would wake up every morning to the anthem "Hello, the Russian people, our great brother, our living genius, Lenin." We have almost forgotten national values like Hayit and Navruz. We never tired of repeating the slogan that the proletarians of the world should unite. All this is reflected in "Lolazor", the tragedy of the nation is revealed in a metaphorical way. Officials who are loyal to the party, whose every action is in line with the standard set by the Communist Party, who love their careers for life, and even the trustworthy people of the state who treat their wives and relatives according to their careers are all cripples of the former alliance. J. Orwell describes the creation of the world described by M.M. Dost as follows: “The world of fear, treachery, and suffering is a world that is becoming more and more merciless, not merciless. Progress in our world is an increase in suffering. Previous civilizations claimed to be built on love and justice. Our civilization is built on hatred ”[1; 253].

When Yakhshibaev saw the professor laughing in Lolazor, his teeth fell out when he learned to laugh, and he lost his teeth when my friend Sharif died. We ate at the funeral that day. when he said, "first we offer our condolences to the widow, then we forget," and then someone else's words, "I will not go, I hate her, I will hate her even after she dies." [2; 26]. These two works, which date back half a century according to the time of creation, are in fact a continuation of each other. The predictions made in the first will happen in the second. The purpose, operation, and essence of the policy of the totalitarian regime have been interpreted in the same way by the writers of the two nations, the two social systems, both inside and outside the prisons of the peoples.

O’Brien says, “There will be no feelings of fear, anger, victory and self-disintegration in our world. We lose everything else. All of them. We will forget the previous way of thinking - the pre-revolutionary era. We have severed the bond between parent and child, between man and woman, between one man and another. We have done so that no one trusts his friend or his wife. ”[1; 253] Given that 100 of the 137 prophecies in Orwell’s books have been fulfilled, our

confidence is heightened that he is as uniquely gifted as the great prophet Nostradamus. Such predictions of masters of artistic expression are not new to history. Suffice it to recall Jules Verne's prophecy about the Titanic. There seems to be an extraordinary inner power in the true creator, an awareness of world events far above grounded perceptions. The possessors of the word (Navoi) who have the power to give life to the dead are people who are unlike others, because creation itself is in fact a heavenly phenomenon. The prophecies of Navoi and Mashrab about their own deaths also confirm our opinion.

Orwell's writings also took place one after the other in the former Soviet state for a long time. During the years of repression and the second post-war famine, people lost faith in each other, and everyone became afraid of each other. From sumalak to blessings for the dead, from funerals to wearing robes and skullcaps, everything was forbidden. As the writer says, anger, fear, self-destruction, the loss of language, religion, faith, entered the way of life of the nation. No one was able to resist, the protesters were shot and persecuted. The girl hears this and sells her father. This event is just a page of the history of our people.

We see the same reality in "Lolazor" in the image of Kurbanoy, Avvalbek. The victim is an ordinary girl who buys pistachios on the street and becomes an advanced picker at the request of adults. He is actively involved in the cotton-picking machine during the harvest season, and with the assignment of his superiors, the press turns him into a star. There is only one happiness, one goal for the Sacrifice, who recognizes neither the land, nor the family, nor the child, and he must always be clothed in glory. Kurbanoy, who is separated from his several children, abandons the unborn baby and joins the mausoleum in the cotton picking machine, because the task of the party is more important to him than his one and only child.

"The Barn" depicts Stalin's bloody and horrific policies, and tells the story of a new lie that forcibly instills the words of truth and equality in the minds of the people and puts pressure on the world. The narration reveals the eternal victory of the strong over the weak, the cunning over the simple, and the evil over the good. The work was banned in the West for two years, until 1945, and was not even allowed to be published in England or America.

In European literature, methods of expressing the supernatural reality in the language and style of the dystopian novel have been studied. This is very important and necessary, because a number of foreign critics (R. Warx, A. Kettle, I. Howe, M. Hodgart, etc.) consider dystopia not as a uniquely valuable artistic phenomenon. It should be noted that these ideas, the critical attitude of literary critics, apply to both the content and the form of the novels. Indeed, J. The language of Orwell's novels is characterized by a certain dryness, false science, lack of vivid figurative means and stylistic devices. Some of the "colorlessness" of the images is primarily explained by the writer's inner atmosphere of the art world. Moreover, in relation to these views, this can be explained by the general scientific problem of the novel. The author, who prioritizes science, convincingly proves that scientific and technical achievements have a direct impact on individuals and society in general. In a technocratic society, its main features are community, similarity and stability, and as an integral property of human nature, language does not change and inevitably changes as a "pillar" of a well-oiled mechanism, that is, a man who has become a bolt of society. He disintegrates himself as he loses his inner 'I', degenerating as a person. In the author's image he makes extensive use of expressive means and various stylistic devices, which is why the novel "1984" differs from other works in this direction. The author's style of writing can be described as impressionistic, with the use of mathematical imagery, metaphors and symbols in the creation of an image of the future being the basis for such a conclusion.

Observing the peculiarities of the writer's uniquely colorful images and portraits shows that he creates the character in a sketch, welding each impression with a strong tattoo and great speed. In general, the analysis of the text of the novel allows us to highlight the following features: the original exposition, that is, the reader is introduced into the world of everyday reality of the non-imaginary situation from the first lines. Typically, such a style is a very convenient and effective way to quickly introduce the reader to the artistic world of the work. When it comes to social science fiction or dystopia, which uses fiction as an artistic medium, this is even more necessary because the authors of fantasy works are meant to create a special world by modeling a special reality that is unfamiliar to the reader. Moreover, at the plot level, such an exposition implies the social and temporal stability of all the described societies, their own system of government, their own laws and orders, and the synthesis of different styles. In our opinion, J. Orwell's purpose in applying such experiments is to present to the student's mind, subconsciously, several alternative variants of reality - an artistic image of "existing," "possible," and "necessary." J. Orwell articulates his ideological goal through the extensive use of individual neologisms that do not cover the description of the daily lives of people in the world of dystopia, but reflect their unique characteristics. This explains why many new words that do not exist in the language are used in his works. The writer chooses the method used in the works of fiction to form an idea of the environment, spirit, its ideology and politics of the future society, and through these words the reader easily adapts to the spirit of the work. The reader quickly realizes a fact that is unfamiliar to him and participates in building the artistic world of the protagonists. On the other hand, their use is closely related to the problem of modeling artificial language, which is designed to shape the thinking and behavior of the population of dystopia. [1; 284-295] Many new language words, such as "Tinchvaz", "Haqvaz", "ishkun", "muhvaz", still do not appear in any oral or written form of any language in the world, such terms are specific only to this work, only to the lexical layer of this novel.

When analyzing a writer's authorial language, several approaches are possible. One of them is functional, i.e., the work being studied is based on the tasks of the genre in which it is written, as Orwell is sometimes involved in journalism in addition to the various genres of fiction, and sometimes the journalistic spirit predominates. In the Orwell style, the rigidity of statements, the figurativeness of images, the methods of giving the impression of contrast, the proximity of paradoxes, biblical words and phrases to oral speech (in one or adjacent sentences), words that must be understood in a completely different sense, unexpectedness, contradictions of ideas (same or two sequences) -sentence) is observed. It should be noted that J. Orwell's style and language are unique, and its scientific study, the study of the author's work from a linguistic point of view is of great importance for translation studies and provides important conclusions.

One of the leading principles in prose in the current literary process is the appreciation of psychology as the main tool in depicting man in all its aspects, in different situations and in different situations - from different angles. Prominent representatives of world literature A. Dante, M. de Servantes, Pushkin, M.Lermontov, F.Dostoevskiy, L.Tolstoy, M.Bulgakov, F.Kafka, A.Kamyu, L.Andreev, J.Joys, H.Hesse, L.Borxes, E.Xeminguey, J Orwell, the study of the works of ChingizAitmatov, confirms that in the works of these writers, artistic psychology is manifested in various ways and means.Our national prose writers A.Qodiriy, Cholpon, A.Qahhor, Oybek, O.Yakubov, P.Qodirov, Sh.Kholmirzaev, O.Mukhtor, M.M.Do'st, H.Do'stmuhammad, N.Eshonqul, E.Azam, Sh. It can be observed that this tradition, that is, artistic psychology, as a method of interpretation in the coverage of the creative concept, is more deeply reflected in the prose works of Butaev, U. Hamdam. This means that psychology has a special place in the development of national prose.

Any artistic expression of the text is distinguished by the fact that it has a certain literary impact on the spiritual-psychological world of man, as well as in the oral or written style. Even if any work of art becomes a perfect work of art, it cannot capture the heart of the reader, it cannot fulfill its most important function - its aesthetic function. The real life of a work of art comes to life only when the spiritual intimacy with the reader begins, acquires a receptive essence. J. Orwell accomplishes two important purposes through the literary text. Firstly, it turns the fate of its protagonists in a completely different direction through more words than events, and secondly, it does not seek the reader, on the contrary, the heart of the reader who captures this novel is shaken, because this work embodies all human problems.

The means of artistic image and expression (portraits, psychological landscapes and details) and "things that are not connected with the world of objects, which are not clearly visible - to express the psyche of the characters" [3, 8] in the novel "1984" , at home, in a dream show, the writer draws the reader closer and closer to himself. The expression of the psyche of the characters is interpreted as a characteristic of style, sometimes of figurative content, or of formal-semantic quality. As a result, it is difficult to come to a firm decision on this issue. In fiction, the writer's skill reveals the spiritual world of the protagonists, or more precisely, the most subtle, most mysterious feelings that run through their hearts.

We see that it is very important to study the creative individuality, poetic form and style of creativity in the works of the artist, the creation of a literary hero and the skills of artistic analysis and research of the psyche of characters on the basis of an integrated literary process. Because the portrayal of a person as a perfect person, a full representative of society, a citizen who has his own views and understands his rights, an active member of society who is not indifferent to his fate, is done for a specific purpose. The essence of this goal should be to build a democratic society, the protection of human rights through the rule of law. This is the main idea of the novels analyzed by J. Orwell and M. M. Dost. The writer's style is evident in the realization of his ideological goal by various means, such as inner monologue, portrait, dialogue, landscape. In 1984, the protagonists are taken to the outskirts of the city, to the church, while in Lolazor, NazarYahshibaev invites Muhsina and his friends to the mountains, the writer takes his friend to the mountains, the dream of creating a garden, his friend's desire for a garden and regretting his garden's neglect. The world is revealed. Multi-layered images represent the novel characters 'attitudes toward the world and man, to the news happening in their own hearts and in society. The construction of the mill in the "barn", working in the fields, taking the sheep to the pasture outside the barn, and the story "Return to Galatepa" depict the steppe, farming, a courtyard surrounded by thick trees, based on the ideological purpose of the artist. All of the above cast a figurative character, helping the reader to understand the spirit of reality.

An examination of Orwell and M.M. Dost's novels reveals that each novel is completely new in style and essence as it interprets time and space, but in both novels the human problem is the main theme, and this is natural. It can be said that the emergence of new means of interpretation in modern Uzbek novels is not only the result of the literary influence of our writers, but also in the legitimacy of the artistic interpretation of social thinking. A. Kadyri's "Last Days", Cholpon's "Night and Day", Oybek's "Navoi", O. Yakubov's "Diyonat", P. Kadyrov's "Starry Nights" introduced our national novel to the world, while Murod Muhammad, created in the literature of independence, Dost's novels "Lolazor", T.Murod's "Fields left by my father", H.Dustmuhammad's "Market", L.Burikho's "People in the heat" novels renew the form and content of Uzbek literature. Literary critic H. Karimov explains this as follows: "It is natural that a change in human thinking is influenced by changes in time and society, which, in turn, determines the right direction of society, reflects its place and status in life and attracts human attention. This is reflected in Uzbek novels. This means that it is not the events themselves, but

the person himself, his thoughts, pains, sufferings, psyche, psychological world that lead, describe and reveal them ”[4, 83].

The works "Return to Galatepa" and "Barn" do not generalize the human personality, but describe each person as a separate role. Because one of the conditions of existence is self-possession, although the destinies of people who do not repeat each other sometimes resemble each other in the example of society or cattle, there is also an individuality in their way of life that belongs only to themselves.

It is noteworthy that the novel "1984" combines the psychological interpretation of the feelings of the heart, soul and mind in the places where such heroes as Winston, O'Brien, Julia, Goldstay are interpreted. The unity of content and form ensures methodological integrity and determines the level of artistry of any work. [5; 82]. The writer often seeks to reveal both the psychological and social nature of the character of the protagonist. We see that Winston’s mutual rapprochement with Julia was not just for fun, but his observations about the tyrannical totalitarian regime that bound them together. Thought brings them closer together, unites two people who aspire to each other because of a spiritual need, a strong hatred for society.

It is known that the style of each writer depends on the nature of talent, creative image, way of thinking, way of expression, attitude to literary traditions. Each artistic element in the non-fiction novel "1984" shows the uniqueness of the writer's style, revealing the peculiarities of the character of the protagonist, as well as a synthesis of social relations, the analysis of the impact of political reality on the characters.

George Orwell's 1984 and The Barn are stylistically complex and written in an unconventional way. In modern terms, they are masterpieces of the modernist style of their time.

It is in this spirit and style that the peculiarities of works are so common in world literature before George Orwell. For example, J. Joyce's "The Adventures of Wellis", F. Kafka's "Process", A. Camus's "The Stranger", M. Bulgakov's "Seeds of Disaster", "Ityurak", "The Master and Margarita", L. Andreev's "Judas Iscariot". In the Uzbek national literature, which artistically synthesizes the modernist traditions of world literature, new approaches to reality are also reflected. Its first buds were "Return to Galatepa or happy Gaybarov" by MM Dost. It can be seen in the works "Lolazor", "Resignation", "Mustafa". Later, this unconventional prose, a relatively complex style, appeared in various forms in the works of T. Rustam's "Game of Butterflies", H. Dostmuhammad's "Jajman", N. Eshonqul's "Coffin", O. Mukhtor's "Fu", "Plato".

APPLICATION OF INNOVATIVE METHODS IN THE PREPARATION OF CHORUS CONDUCTOR

HayitoSv Obloqul Aliqulovich*

*Lecturer,
Department of Music Education Navoi State Pedagogical Institute,
Faculty of Art History, UZBEKISTAN

ABSTRACT

At present, the attention and need for the chorus is becoming more and more important in our cultural and educational life. Education is rising to a high technological level, the development of new pedagogical technologies continues, which is primarily due to the idea of the integrity of the pedagogical process. At the heart of this article lies the main task of training a, to form a muscular freedom of students, to cultivate a holistic personality who is passionate about their profession, striving for self-improvement.

KEYWORDS: *Professionalism, Creative Approach, Conducting, Individual, Potential, Innovation, Chorus Conductor.*

INTRODUCTION

In the middle stage, the system of training choirmasters in the specialty "Choir Conducting" is individual, there are no classes with the choir directly in the classroom. Often the exercises are of an associative nature, with the ability to express and control the chorus sound. In the process of training conductor choirmasters, modern science makes extensive use of various musical and pedagogical technologies, the use of which serves to develop and diagnose the professional and personal qualities necessary for the future career of the student.

In particular, the Action Strategy for the five priority areas of development of the Republic of Uzbekistan for 2017-2021 states that deepening and increasing their social activity in the development of civil society.[1]The modern pedagogical process is inconceivable without the widespread use of new information and communication technologies. Great interest in modern computer systems is the motivational basis for educational activities. It is information technology that is the basis of modern education and guarantees the required level of quality, variability, stratification and individualization of teaching and education.

Computers are a valuable source of bibliographic and encyclopedic information in the preparation of lectures on special education, such as music teaching methods, choral literature, choral studies. Types of computer music curricula used in the course include: electronic textbook, electronic music encyclopedia, library information retrieval systems.

Computer programs are also used in the development of musical ability, while in the study of choral parts exercise programs that determine the height of the graphic to control the purity of vocal intonation are indispensable. References, which contain audio files of musical works, allow you to listen to the studied choral works. Programs that allow students to type and edit a musical text in choral arrangement, prepare a vocal work for publication on piano accompaniment, prepare a score for a vocal or instrumental ensemble of any composition are indispensable. A computer that uses television equipment can also act as a "simulator" for transmission. Teachers can use a variety of knowledge control programs to master the subject.

Game technology is widely used in specialty training, with a focus on communicating with other participants, collaborating, coordinating their actions, sharing knowledge, expanding and deepening it. You can organize classes in groups in the classroom. One of the founders of the Kazakhstan School of Opera and Choir, Professor Jamanbaev B.A. suggests organizing classes in groups from the first year of study. Such classes have a number of advantages: the educational and pedagogical tasks set by the teacher with the participation of students will be effective in nature; the mistakes of one are taken into account by the others and corrected more quickly and efficiently; solidarity among students, "frienda special psychological climate is created that shapes the "sense of belonging", mutual support and community involvement.

Group sessions allow conducting exercises not under the piano, but in a vocal ensemble composed of the students themselves, where each of them works as a choir member and choirmaster. Along with the formation of willpower qualities that play a major role in the conducting profession, the principles of personal development in the team are being successfully implemented. The role of students in analyzing specific situations together is to reflect on their actions, analyze failures, record positive moments, and develop a new syllabus for the lesson.

Problem-based learning technology shapes the relationship between the composition being studied and other related phenomena of music and art culture. The performance of the same work by different choir groups is compared and analyzed by the students. In the classroom, you can use the "elegant text" method, its simpler modifications - "partial text justification" and "text processing". All of this is done by the dynamic recordings that the student has to make, or he or she adds detailed additional comments to the score, encrypts and concretizes the proposed authorial version of the play, and creates his or her own performance plan. A detailed study of musical material and the use of specific terminology places the need for the student to constantly refer to dictionaries and other reference books, which, in turn, leads to a more meaningful study of musical material. The student's activity is focused on solving the problem when he or she sees the conditions necessary to overcome it.

Developing a scenario of a musical event for school students as part of practical or extracurricular activities, selecting and designing works on the repertoire, leads to project learning technology.

Choral work analysis technology leads to a collaborative design and prediction process of choral cycle work. The analysis includes: general information about the authors of the music and the artistic text; musical theoretical analysis taking into account the basics of the musical text; vocal-choral analysis with the study of overcoming difficulties in performance; to analyze the idea of the conductor of the authors of the work, taking into account the image.

The problem of maintaining and strengthening the health of students has been around for a long time and requires the use of health-saving technologies in teaching choral singing. Music therapy is becoming a world-renowned science today. Song is a powerful means of balancing the nervous system, psyche, prevention of diseases of the vocal apparatus and respiratory organs, has a beneficial effect on the broncho-pulmonary system, kidneys, and massages the throat, thyroid

gland, heart. A large load is massaged diaphragm, intercostal muscles, abdominal muscles, resulting in internal organs.

In the choir class work, “Respiratory Gymnastics” recreates the respiratory stereotype created as “a method of treating diseases associated with voice loss.” "Articulation gymnastics", "intonation-phonetic exercises" of V. Yemelyanov'sphonopedic method of voice development; Caring for purposeful and proper development is an integral part of the choir class.

Music-pedagogical technologies not only help to develop the professional and personal qualities of the student, but also optimize the learning process, making it interesting and flexible. This does not mean that a lesson in conducting class should become fun for students, but that if the student is interested in the results of their work and the learning process itself engages the student, self-improvement a socially successful person is formed.

Each teacher of the “Choir Conducting” cycle discovers new exciting opportunities in their professional activities using modern innovative technologies in the context of modernization, as in the process of training a choirmaster, as a result of which for the teacher - work, and for students - learning becomes more cognitive and engaging.

ABSTRACT

Heart disease is one of the leading causes of death across the globe, and it is critical to detect the illness early on. The doctor may use computer-assisted tools to anticipate and diagnose cardiac problems. The goal of this study is to raise awareness about heart-related cardiovascular illness and to provide a short overview of current decision support systems that use data mining and hybrid intelligence methods to forecast and diagnose heart disease.

KEYWORDS:*Cardiovascular Disease, Data Mining, Decision Support System, Hybrid, Intelligent System.*

4. INTRODUCTION

The heart is a major muscle organ in humans that pumps blood via the circulatory system's blood vessels [1]. The correct functioning of the heart is essential for human survival. The heart's dysfunction will have an impact on other areas of the human body, such as the brain and kidneys. When blood circulation in the body is poor, it affects both the heart and the brain. Blood arrest in the heart is often referred to as an attack, whereas blood stoppage in the brain is referred to as a stroke. The proper functioning of the heart and brain is vitally necessary for human existence.

4.1. Cardiovascular Disease:

For both men and women, cardiovascular heart disease is one of the leading causes of mortality. The phrase "heart disease" refers to a variety of heart-related medical disorders that describe irregular health problems that directly stimulate the heart and all of its components[2]. Table 1 lists the many kinds of heart-related cardiovascular illnesses and their descriptions.

TABLE 1. TYPES OF CARDIOVASCULAR DISEASES [3]

Heart-related cardiovascular diseases	Description
Acute coronary syndromes	Blood-supply to the heart muscle is swiftly obstructed
Angina	Chest pain due to a lack of blood to the heart muscle
Arrhythmia	Atypical heart rhythm
Cardiomyopathy	Heart muscle disease
Congenital heart disease	Heart disfigurements that are present at birth
Coronary heart disease	Arteries supplying blood to heart muscle becomes obstructed
Heart failure	Heart is not propelling ample blood
Inflammatory heart disease	Tenderness of the heart muscle and/or the tissue
Ischaemic heart disease	Plaque builds up inside the coronary arteries
Rheumatic heart disease	Rheumatic fever
Valvular disease	Disease of the valves

Table 2 lists several risk factors and their symptoms that lead to a heart attack.

TABLE 2. RISK FACTORS AND SYMPTOMS OF HEART ATTACK[4]

Risk factors	Symptoms of Heart Attack
• Age • Angina • Blood cholesterol levels • Diabetes • Diet • Genes • Hypertension • Obesity • Physical Inactivity • Smoking • Work stress	• Chest Discomfort • Coughing • Nausea • Vomiting • Crushing chest pain • Dizziness • Dyspnoea (shortness of breath) • Restlessness

4.1.1. Prevalence of Heart Disease:

According to global life expectancy, India is the 39th most vulnerable country to coronary heart disease in the world. The mortality rate per 100,000 in India is 138.36[5]. Table 3 shows the number of people in India with coronary heart disease by age, gender and location.

TABLE 3. CORONARY HEART DISEASE IN INDIA BY AGE, GENDER AND REGION[6]

Year/Age	20-29	30-39	40-49	50-59	Male	Female	Urban	Rural
2000	4.51	5.48	6.11	5.81	12.9	14	12.3	14.7
2005	6.15	7.25	8.33	7.71	17.1	18.7	17.8	18
2010	8.31	9.09	10.9	10	22.4	24.5	24.6	22.2
2015	10.4	12.4	14.3	13	28.7	32.7	36	25.4

The following table shows that in a nation like India, women are more likely than males to suffer from coronary heart disease. Until 2010, the population of India's rural regions suffered from coronary heart disease at a higher rate than the urban population, however this trend has reversed after 2010. In 2015, there was a significant difference in the number of people suffering from CHD in rural and urban areas.The following is the format of the paper: Section 1 is an introduction that covers cardiovascular disease and its prevalence. The advantages of employing a decision support system to predict cardiac illness are discussed in Section 2. Sections 2 and 3 discuss several data mining and hybrid intelligence techniques for predicting cardiac disease. Finally, Section 3 brings the paper to a close.

5. DISCUSSION

In India, the population between the ages of 40 and 49 is severely affected by heart disease. In the past fifteen years, the number of people suffering from heart disease has increased across all age categories. Coronary heart disease in India by age, gender, and region is shown in the graph below.

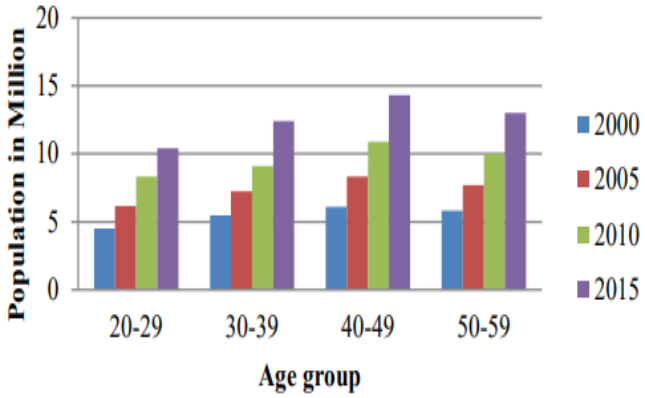

Figure 1. Illustrates the Coronary Heart Disease in India by Age[7]**.**

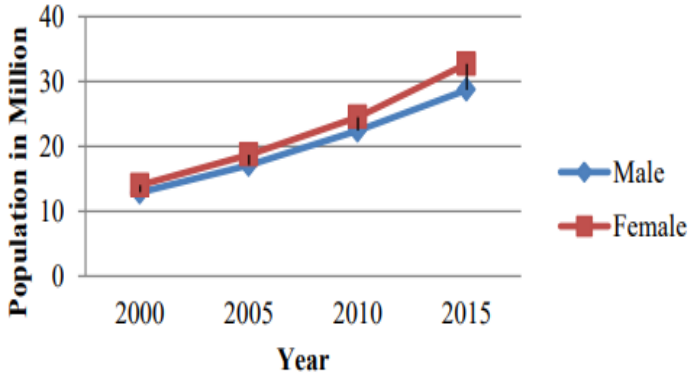

Figure 2. Illustrates the Coronary Heart Disease in India by Gender[7].

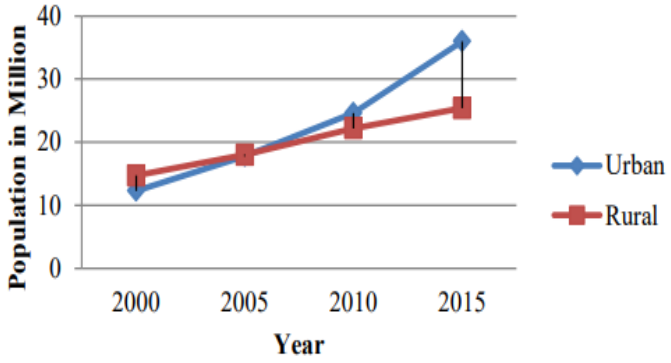

Figure 3. Illustrates the Coronary Heart Disease in Urban and Rural India[7].

5.1. Decision Support System (DSS) for Heart Disease Prediction and Diagnosis:

The use of computer-based systems and algorithms that make judgments at the right stages may help enhance medical diagnosis. Decision support systems are the name given to such systems (DSSs). Intelligence has a part in this as well. Based on patient data and domain expertise, these systems may assist anticipate and diagnose illness. DSS aids in the improvement of healthcare quality by delivering accurate and reliable diagnosis. DSS may minimize treatment costs by delivering a more precise and quicker diagnosis, as well as saving time when compared to conventional treatments. Any health organization may use these services after they've been uploaded to the cloud.

5.1.1. Knowledge Discovery in Database:

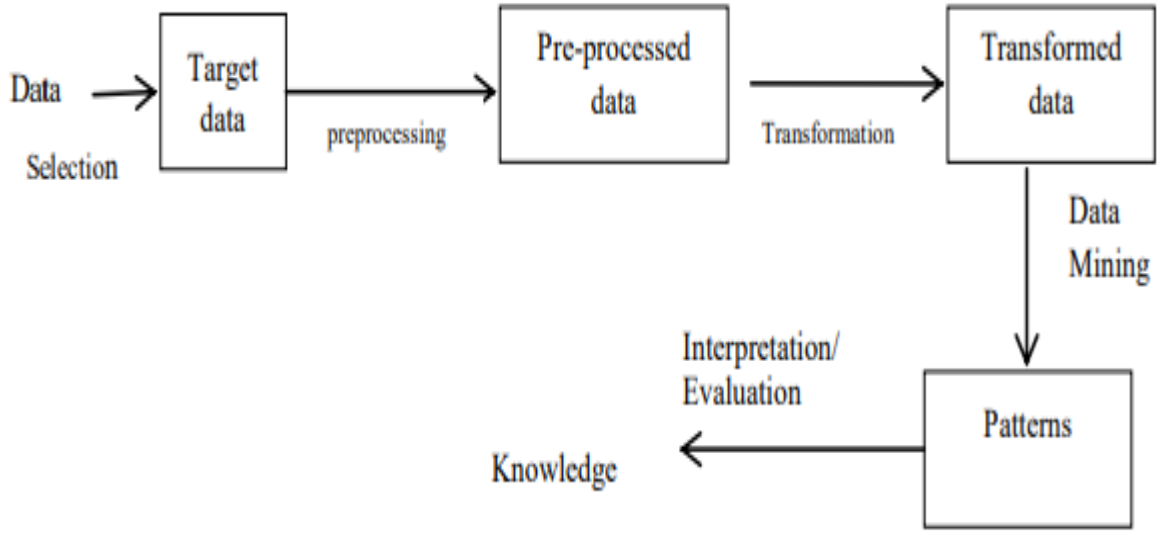

Figure 4. Basic database knowledge discovery technique

A knowledge base was used to create decision support systems. The data mining method collects valuable information from a data collection and converts it into a suitable structure for future use in database knowledge discovery. To uncover hidden patterns and connections from huge datasets, data mining combines statistical analysis, machine learning, and database technology. Data mining is the process of extracting implicit, previously unknown, and possibly valuable information from data recorded in a database in a nontrivial way. There are two types of learning methods used in data mining: supervised and unsupervised learning. In supervised learning, a training set is utilized to learn the model parameters, while in unsupervised learning, no training set is needed.

5.1.2. Data Mining Algorithms:

- *Neural Networks (NN):*

A neural network is a parallel, distributed information processing structure made up of a large number of processing units known as nodes that are linked together by unidirectional signal channels known as connections. Each processing element has a single output connection that branches out into many connections, each of which transmits the same signal. According to how they learn, the NN may be divided into two categories. There are two types of learning: supervised and unsupervised.The network computes a response to each input in supervised learning and compares it to the goal value. If the calculated answer does not match the goal value, the network's weights are adjusted using a learning rule. Single-layer perceptron and Multi-layer perceptron are two examples of supervised learning. Unsupervised learning allows networks to learn by recognizing unique characteristics in the issues they are presented with. Self-organizing feature maps are an example of unsupervised learning.

- *Naïve Bayesian Classifier:*

The Bayes theorem-based Nave Bayes classification method generates a probability by measuring the frequency of values and combinations of values in historical data. The Bayes theorem calculates the likelihood of an event happening given the probability of a previous occurrence.

Pro(B given A) = Pro(A and B)/Pro(A)

This method has the advantage of using just a minimal quantity of training data to estimate the parameters needed for classification.

- *Decision Tree:*

A decision tree is a framework that may be used to break down a big collection of data into smaller groups of records using a series of basic decision rules. The members of the resultant sets grow more and more similar to one another with each division. One of the decision tree models that generates a decision tree from a given set of training cases is ID3 (Iterative Dichotomiser 3). C4.5 is the most recent version of the ID3 induction method, C5.0 is an extension of the C4.5 decision tree algorithm, and J48 is the ID3 algorithm's implementation.

- *Genetic Algorithm:*

Genetic Algorithm is a search method in Artificial Intelligence that employs natural selection. Genetic algorithms use methods including inheritance, mutation, selection, and crossover to solve optimization and search issues. A typical genetic algorithm necessitates a genetic representation of the solution domain as well as a fitness function to assess it.

5.2. Surviving Techniques for Prediction of Heart Disease using Data Mining:

It is suggested to develop a Web-based clinical decision support system that utilizes medical profiles such as age, blood pressure, and other factors to forecast the likelihood of individuals developing heart disease. The Nave Bayes Data Mining technique responds to complicated what-if scenarios. The system is built on the PHP framework, which is adaptable, dependable, and extensible.By analyzing previous researcher's results, a study on various data mining methods used for the prediction of heart disease showed hybrid approaches to be the best prediction model compared to single models.

TABLE 4. ILLUSTRATES THE COMPARISON OF HEART DISEASE PREDICTION SYSTEM USING DATA MINING CLASSIFICATION TECHNIQUES[8]–[11]

Reference	Data Mining Techniques Compared	Accuracy Obtained		Number of Attributes used	Result: Best technique
Purusothaman G *et al* (2015)	Single data mining models: Decision Tree	76%			Hybrid model
	Associative Rules	55%			
	K-NN	58%			
	Artificial Neural Networks	85%			
	Support Vector Machine	86%			
	Naïve Bayes	69%			
	Hybrid models	96%

Gnanasoundhari SJ *et al* (2014)	Naive Bayes	52.33%			Weighted Associative Classifier
	Neural network	78.43%			
	Weighted Associative Classifier	81.51%			
	Support Vector Machine	60.78%			

Author assessed three data mining methods, including Decision Tress (C4.5), neural networks (MLP), and Nave Bayes, using accuracy and sensitivity as metrics. The results show that neural networks and Nave Bayes perform better than Decision trees when there are more characteristics. The top performers are neural networks, which have a classification accuracy of 0.897 and a sensitivity of 0.9017. The effectiveness of several decision tree algorithms used for heart disease categorization and prediction, such as ID3, C4.5, C5.0, and J48, has been investigated. ID3 is a decision tree model that uses a fixed set of training examples to create a decision tree. C4.5 is the most recent version of the ID3 induction method, C5.0 is an extension of the C4.5 decision tree algorithm, and J48 is the ID3 algorithm's implementation. The author also included attribute selection criteria, such as information gain, Gini Index, and Gain ratio, as well as performance assessment criteria, such as sensitivity, specificity, and accuracy.Because the heart dataset includes huge volumes of data that take longer to classify, attribute selection techniques are used to decrease the dimensionality of the data. The Nave Bayes classification method improved the outcomes in both instances. When the performance of four classification algorithms: Nave Bayes, Decision Tree, K-NN, and Neural Network is compared on a full and reduced heart disease dataset, this is seen.

5.3. Surviving Techniques for Prediction of Heart Disease using Hybrid Intelligent:

For predicting cardiac disease, a genetic algorithm and fuzzy logic methods are employed, with the genetic algorithm doing feature selection and the fuzzy logic performing classification and prediction. Using measures such as accuracy, specificity, and sensitivity, the authors compare the

performance of the suggested approach (GAFL system) with that of the fuzzy entropy-based method (NNTS). The suggested method's accuracy is 86 percent, and the number of characteristics is decreased from 13 to 7.In this paper, we propose an Intelligent Heart Disease Prediction System based on CANFIS and Genetic Algorithm. The neural network, fuzzy logic, and genetic algorithm are all used in this model. The suggested model improves training efficiency and classification precision.

The authors proposed a novel classification method for cardiac disease that incorporates Artificial Neural Networks and feature subset selection. The number of characteristics is reduced when feature subsets are selected. Principal Component Analysis is used for pre-processing (PCA). The results show that the suggested method outperforms conventional classification approaches in terms of accuracy.Gupta et al.'s goal is to utilize a genetic algorithm to determine the weights of neural networks and to compare and contrast two kinds of learning algorithms: the Feed forward neural network algorithm and the Fitting algorithm[12]. By using datasets on Feed Forward ANN model, Fitting ANN model, and GA trained Feed Forward ANN model, GA trained Fitting ANN model, and the author validated the accuracy to be 97.75 percent and the improvement of Feed-forward and Fitting neural networks to be 1.29 percent and 1.37 percent, respectively.

Three data mining classification methods (Decision Trees, Naive Bayes, and Neural Networks) are utilized, as well as two additional characteristics: obesity and smoking, as well as a set of 13 consistent attributes. We utilized the J48 decision tree algorithm, which utilizes the pruning technique for tree construction, and the data mining application Weka 3.6.6. When comparing the accuracy of classification methods with 13 and 15 input characteristics, the findings indicate that neural networks provide correct answers. The accuracy is improved using Multi-layer Perceptron Neural Networks (MLPNN).The cerebrovascular illness is classified using artificial neural networks and the back propagation error technique. The neural network was trained with 16 input characteristics using a back propagation method on one hidden layer with a sigmoid function to enhance accuracy.

6. CONCLUSION

There are many decision support system that use different methods to predict heart disease. According to global data on life expectancy, heart illness is becoming increasingly prevalent. As a result, it is essential to develop a cost-effective, intelligent, trustworthy automated system that correctly predicts cardiac disease based on symptoms, gender/age, and domain expertise of experts in the area.

ABSTRACT

One of the most essential components of an electronics device is the logic gate, which performs an action between two or more inputs and produces just one logical output. In this article, we present a circuit that employs a bipolar junction transistor in conjunction with seven logic gates: AND, OR, NOT, NAND, NOR, XOR, and XNOR. The circuit is constructed by using two digital signals as input terminals, labeled "A" and "B." With each individual logic gate, this approach will reduce individual circuit use. The primary benefit of this article is that it simplifies circuit design due to the usage of a bipolar junction transistor in this project. The logic gates are electrical devices that implement a Boolean function and create a single logical output by conducting logical operations between two or more inputs, according to this article. In this logic gate, the digital signal enters via the input signal and leaves through the output signal. A logic gate has two inputs and one output terminal in general, but the input signal may vary and include many signals.

KEYWORDS:*Bipolar Junction Transistors (BJT's), Integrated Circuits (Ics), Diode, Zener Diode.*

1. INTRODUCTION

Logic gates are electrical devices that implement a Boolean function and generate a single logical output by performing logical operations between two or more inputs. The digital signal enters via the input signal and exits through the output signal in this logic gate. In general, a logic gate has two inputs and one output terminal, although this input signal may change and may contain more than two signals. However, there is a NOT gate that has just one input and one output and works in binary terms[1].

The data is not gated in such a way that if the input signal is active high, the output signal is active low. We can combine as many logic gates as we need to build the circuit to get circuits like flip flops, multiplexers, latches, counters, and so on. We can improve the circuit's efficiency by integrating this logic gate and designing it with bipolar junction transistors.[2].

1.1 Types of Logic Gates in the Circuit:

AND: An and gate is a simple digital logic gate that operates according to the truth table, with "0" representing the low signal and "1" representing the high signal. The AND gate's job is to determine the lowest value between two binary digits. With the implementation of logical conjunction, if the input A has a low signal, i.e. "0," and the input B is likewise low "0," the output Y will be low "0," according to the truth table in Figure 1 [3].

When input A is a low "0" and input B is a high "1," the output Y is also a low "0." If one of the inputs is low and the other is high, the output will stay low; but, if both inputs are high, i.e. input A is high "1" and input B is likewise high "1," the output will be high "1." With the logical function, we can state that if the input is high, the output will be high[4].

INPUT A	INPUT B	OUTPUT Y = A.B
0	0	0
0	1	0
1	0	0
1	1	1

Figure 1: The above figure represents an AND logic gate and truth table which represents the function of the gate.

OR: The OR gate is a digital logic gate that operates on the basis of logical disjunction. The logical OR gate's primary purpose is to determine the greatest value between two binary digits. [5]. According to the truth table (Figure 3), if both inputs A and B are low "0," the output will be low "0," but if either input is high "1," the output will be high "1." For example, if input A is a high “1” and input B is a low “0,” the operation Y = A+B will produce a high signal (Figure 2)[6].

Figure 2: An OR gate logic circuit with two input digital signal and one output digital signal.

INPUT A	INPUT B	OUTPUT Y = A+B
0	0	0
0	1	1
1	0	1
1	1	1

Figure 3: The above table is an OR gate truth table. It shows the functionality of the circuit.

NOTE: The logic gate NOT is basically a single input inverter which changes the input digital signal data "1" to an output digital data "0" and when the input data is "0" then the output is "1" (Figure 4). It performs the inverted or complementary function as a logical operation so NOT gate is commonly known as inverter because of its inverting functionality. The inversion is indicated as the bubble symbol on the output terminal of the logic gate (Figure 5)[7].

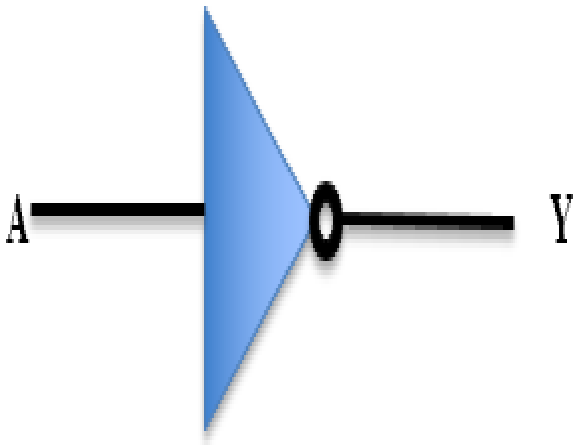

Figure 4: A NOT gate logic circuit which has only one input and output terminal. The output result is the compliment of the input signal.

INPUT A	OUTPUT Y = $\overline{A}$
1	0
0	1

Figure 5: The table shows the functionality of the NOT logic gate, which gives the compliment result of an input signal.

NAND: The NAND gate is a combination of the NOT gate and the AND gate in digital electronics. It generates a complimentary value of the outcomes, for example, if the inputs A and B are both low "0," the and gate will conduct a logic conjunction first, and the output will be low "0" (Figure 6). Because the NAND gate is a combination of NOT + AND, as we said in the first paragraph, the NOT gate produces the complementary of the outcomes[8].

As a consequence, we may claim that the NAND gate enhances the performance of the and gate inside it. Only if all of the inputs are high will the output result be low, and only if any of the inputs are low will the output result be high. De Morgan's theorem is used to create a NAND using a transistor and a junction diode, with two input NAND gate logic defined as Y = A+B, and then the NOT gate operation is used to make it equal to an inverter (Figure 7)[9].

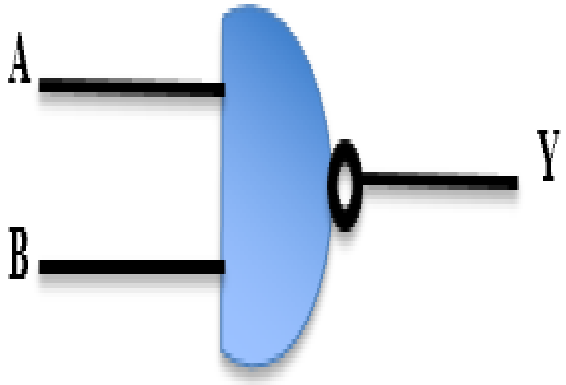

Figure 6: A NAND gate logic circuit which performs the result with combination of NOT gate + AND gate.

INPUT A	INPUT B	OUTPUT Y = $\overline{A.B}$
0	0	1
0	1	1
1	0	1
1	1	0

Figure 7: The above table represents the functionality of the NAND logic gate which fulfill the result with the combination of NOT + AND gate.

NOR: The NOR gate is a logic gate that combines the NOT and OR gates. A bubble is attached to the NOR gate's output terminal, which acts as an inverter. When both the input and output are low or negative, it produces a positive outcome, i.e. a high output. Like the NAND gate, the NOR gate is sometimes known as the universal gate because it may be used to create any logic gate (Figure 8). To begin with, when any of the input digital signals is high, the output will be high, but the NOR gate acts as an inverter, complementing the output data produced by the OR gate. With the logical operating function of the gate, however, when both the input digital signal and the output digital signal are low, the output will be high (Figure 9)[10].

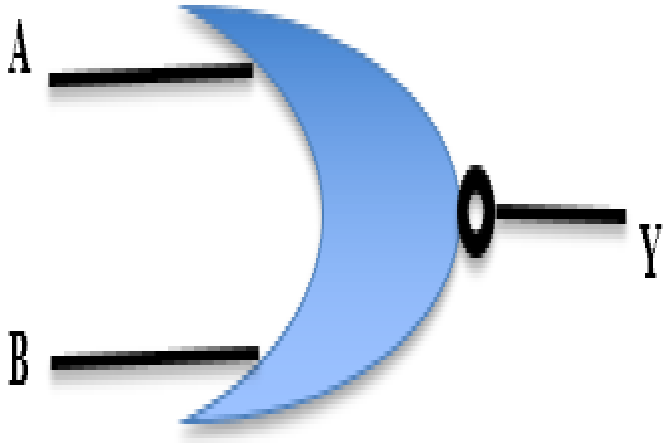

Figure 8: A NOR gate logic circuit which performs the result with combination of NOT gate + OR gate.

INPUT A	INPUT B	OUTPUT $Y = \overline{A+B}$
0	0	1
0	1	0
1	0	0
1	1	0

Figure 9: The above table represents the functionality of the NOR logic gate which fulfill the result with the combination of NOT + OR gate.

The Figure 10 shows the overall combination of the various types of logic gates with their expression equationwhich shows the AND, OR, NOT, NAND and NOR gates expression and symbol.

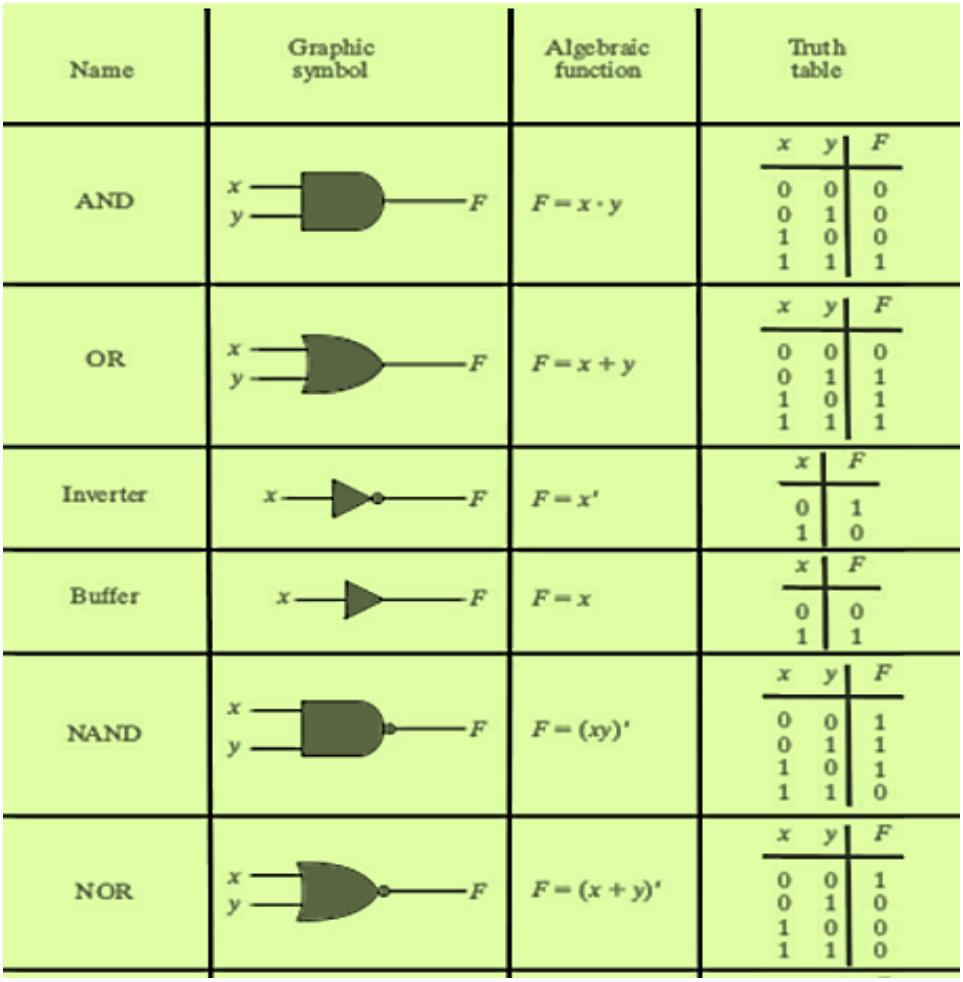

Figure 10: The Overall Combination of the Various Types of Logic Gates with their Expression Equation

REVIEW OF LITERATURE

Mallampati Krishna Prasad et al. devised a bipolar junction transistor (BJT) circuit that provides output for four logic gates, including AND, NAND, OR, and NOR, by accepting two inputs, "A" and "B." They previously created a circuit with just one circuit for each logic gate, but now they have developed a new circuit with four logic gates in a single circuit. They were able to reduce the size of the particular circuit using this approach. They utilized a single IC for all four logic gates instead of four ICs for four logic gates so that the space taken up by the other three circuits might be used for something else. To make the circuit simple to build, this project utilized six bipolar junction transistors [2].

Ashutosh Ghosh et.al studies Picric acid (PA) is a severe water contaminant at low concentrations. Aside from that, aliphatic alkali metals (AAs) add to the list of pollutants that contaminate surface water. There are many reports available to identify PA with an extremely low detection limit (LOD). However, only a few efforts have been shown to identify AAs.

A novel fluorescent donor-acceptor molecule with intrinsic intramolecular charge transport (ICT) has been synthesized, allowing for the selective and sensitive colorimetric detection and quantitation of PA and AAs in nonaqueous and aqueous solutions with low LODs. A hemicyanine skeleton with two pyridenylmethylamino groups at the donor end and a benzothiazole moiety just at acceptor end is used to make the synthesized chemical. Spectroscopic explanations and computational assistance are provided for the detailed processes

and reaction kinetics. The detecting compound's fluorescence characteristic emerges as result of PA protonation of its pyridinyl centers, which causes quenching of fluorescence and subsequent de-protonation by AAs, which restores the signal. By using consecutive interactions, we were able to create logic circuits using the collected optical responses.

Guinevere Strack et.al studies Boolean logic processes are shown using biochemical organisms. AND, OR, XOR, with InhibA were created utilizing soluble chemicals as chemical "devices" as well as the enzymes oxidase (GOx), glucose dehydrogenase (GDH), alcohol dehydrogenase (AlcDH), and microperoxidase-11 (MP-11) as input signals to the logic gates. The enzyme were utilized as both solvent molecules and biocatalysts that were immobilized. The technologies under investigation are thought to be a first step toward the development of "smart" message materials with constructed Boolean logic.

DISCUSSION

This paper discusses about the logic gates which states that the Logic gates are electronic devices that implement a Boolean function and produce a single logical output by performing logical operations between two or more inputs. The digital signal enters through the input signal and exits through the output signal in this logic gate. In general, a logic gate has two inputs and one output terminal, although this input signal may change and may contain more than two signals. However, there is a NOT gate that has just one input and one output and works in binary terms.

An and gate is a simple digital logic gate that operates according to the truth table, with "0" representing the low signal and "1" representing the high signal. The AND gate's job is to determine the lowest value between two binary digits. With the implementation of logical conjunction, if the input A has a low signal, i.e. "0," and the input B is likewise low "0," the output Y will be low "0," according to the truth table.The OR gate is a digital logic gate that operates on the basis of logical disjunction.

The logical OR gate's primary purpose is to effectively identify the maximum between two binary digits.The NAND gate is a combination of the NOT gate and the AND gate in digital electronics. It generates a complimentary value of the outcomes, for example, if the inputs A and B are both low “0,” the and gate will conduct a logic conjunction first, and the output will be low “0.” Because the NAND gate is a combination of NOT + AND, as we said in the first paragraph, the NOT gate produces the complementary of the outcomes. The NOR gate is a logic gate that combines the NOT and OR gates. A bubble is attached to the NOR gate's output terminal, which acts as an inverter. When both the input and output are low or negative, it produces a positive outcome, i.e. a high output. Like the NAND gate, the NOR gate is sometimes known as the universal gate because it may be used to create any logic gate.

CONCLUSION

In this paper we can conclude that with the combination of all the logic a circuit is designed which perform all the task using single circuit where in all the gates can perform at the same time or can perform one after another as per the requirement. The main aim of this paper is to reduce the space which was needed for each circuit for each logic gates. And the most important thing is now the users don’t have to remember the ICs number that which IC is required to perform which task. They can easily perform the task by using the single circuit.

ABSTRACT

The domestication of livestock animals, as well as a lengthy history of migrations, selection, and adaptability, has resulted in a vast array of breeds. Demographic characterization, documentation of production settings, and efficient data administration are all necessary for the maintenance of these genetic resources. Furthermore, molecular genetic investigations enable the assessment of genetic diversity between certain breeds, as well as the reconstruction of breed and ancestral population histories. Cattle, yak, water buffalo, sheep, goats, camelids, pigs, horses, and chicks have all been summarized. Developments in molecular technology are anticipated to aid future development. Nowadays, the breed serves as the conservation unit. Breeds, on the other hand, are social entities that play a role in regional and national identity, leaving space for subjective assessments of their distinctiveness. Breed distinctiveness isn't always apparent from molecular data. These consistently indicate that the breeds share the majority of the variety, with the majority of them harboring a significant portion of the species' overall diversity.

KEYWORDS:*Databases, Domestication, Farm Animal Genetic Resources, Genetic Diversity, Livestock, Production Environment Recording.*

INTRODUCTION

Animal domestication was a crucial stage in the demographic and cultural evolution of humans. It provided the groundwork for modern agriculture, along with the breeding of plant species. The

major evolutionary processes of mutation, artificial selection, adaptability, isolation, and biological evolution have produced an immense variety of local populations throughout the following history of cattle. This has resulted in the development of numerous well-defined breeds utilized for a number of reasons with varying degrees of performance in recent decades. The development of and increasing emphasis on more efficient selection programs has expedited genetic progress in a number of breeds during the past several decades. The spread of genetic material has been aided through artificial insemination and embryo transfer[1]. Furthermore, advances in feed technology have enabled optimum nutrition, and improved transportation and communication systems have resulted in homogeneous and tightly regulated production settings. As a consequence, high-yielding breeds have taken their position throughout the globe. Concerns about the eroding of genetic resources have grown as a result of this trend. Low-production breeds are deemed important for future breeding choices because their genetic diversity is likely to contribute to present or future characteristics of relevance. Comprehensive understanding of the breeds' features, including data on demographic size and structure, geographical distribution, the production environment, and manuscript and between-breed genetic variation, is required for effective management of farm animal genetic resources. Integration of these many kinds of data will result in the most accurate depiction of biological variety within and across breeds, allowing for more efficient FAnGR management[2].

The present level of knowledge on the assessment of biological diversity of the major farm animal species is reviewed in this paper. The sections on demographic characterization and recording of the production environment concentrate on data needs and describe the present status of data availability[3]. After that, there's a look at breed description databases, which briefly explains the data management architecture and highlights the many kinds of publicly available phenotypic and demographic data. For cattle, water buffalo, goats, sheep, horses, pigs, camelids, yak, and chickens, the section on genetic characterization in livestock briefly covers current information about domestication processes and breed variety at the global and local levels. A following section discusses the databases available for storing and managing molecular data. We end with an evaluation of the infrastructure required for thorough studies of global livestock variety, as well as future possibilities.

Characterization of the Population

Demographic data are essential for determining the risk status of livestock breeds, which is an important stage in FAnGR management's strategic planning. Several variables influence one's risk status. For starters, it is related to the population's size and structure. The recommended metric for determining risk status is effective population size, which is calculated using the magnitude of both the female and male breeding populations. Knowing the Ne enables one to estimate the rate of inbreeding and, as a result, the loss overall genetic diversity within a population. Second, risk status is determined by present and anticipated demographic patterns. A fast downhill trend, for example, suggests a high degree of danger. The population's geographical distribution is the third important element to consider. A population that is more concentrated is more susceptible to localized catastrophes, such as disease outbreaks, than a population that is more dispersed. The demographic statistics collected at the national level must be viewed in the perspective of the breeds' worldwide demography. A subspecies that is widespread in other nations is likely to have a lesser conservation priority in the United States. Knowing if a particular national breed is genetically unique or part of a broader population distributed across many nations is a fundamental need. Breeds found in just one country are classified as local breeds, while those found in several countries are classified as transboundary breeds, with the latter being further divided into regional and international transnational breeds depending on the degree of their occurrence[4].

Information can be gathered at least once every generation of the animal in issue, especially for breeds designated as endangered: about 8 years for horses and donkeys, 5 years for cattle, buffalo, sheep, and goats, 3 years for pigs, and 2 years for poultry species. The contraceptive technique being utilized has an impact on the necessary frequency, which should be documented as part of the monitoring procedure. Even while demographic data is available for many breeds, especially in poorer nations, it has not been updated in a long time. The techniques used to gather the data have an impact on their dependability, but the expenses must also be considered. Textual data detailing breed distribution that has been input into DAD-IS is being transformed into georeferenced dimensions; more thorough dereferencing is considered as a priority as element of the deployment of established production environment descriptions[5]. The development of techniques for statistically representative of national animal populations in order to determine their overall population numbers and other census characteristics in a cost-effective way is one of the key problems for the future.

Production Environment Recording

Many elements of FAnGR management need descriptions of breed production settings. They may be used to infer breed traits based on the premise that exposure to various climates, feed supplies, and diseases has resulted in genetic variations in adaptability to environmental circumstances through time[6]. For meaningful assessment and comparison of something like the performance of various breeds, a detailed description of the manufacturing environment is also required. More generally, a better knowledge of production settings – including socioeconomic factors like markets – may aid in the planning of future breed usage and development. While accounts of specific breeds' production settings may be obtained (with different degrees of concentration and depth), comparisons are difficult, and breeds are typically regarded in isolation from their manufacturing surroundings.

A production environment is split into two major areas in the proposed framework: the management environment and the natural environment. These areas are further subdivided into a criterion hierarchy. On global high-resolution maps, the majority of the measurements needed for the important ecological domain are already accessible. By combining these data with spatially distributed breed distributions, more detailed descriptions and analysis of the production settings will be possible.

Databases of Breed Descriptions

The creation of awareness via the distribution of knowledge is seen as a critical component in the conservation and use of genetic resources. As a result, a number of websites have attempted to address this problem, frequently from various angles. There are three types of databases to consider: To begin, breed organizations maintain webpages to explain their populations in order to promote their own genetic resources. The perceived strengths of a breed are highlighted, but they are not necessarily backed up by facts and statistics. The websites, on the other hand, provide a helpful and comprehensive overview of a certain group of breeds, sometimes with pictures, but their reach may be restricted due to the usage of the national language[7]. It contains information on the breed's history, the breed society, and a summary of the breed's recognized strengths, also including High Daily Weight Gains and Longevity. Again, a visually attractive presentation could get more attention than hard data. Third, there are just a few websites accessible on a global scale.

Because all FAO member nations have committed to submit their breed data to DAD-IS, now the FAO node of FABISnet, via their officially designated National Coordinators for the Management of Animal Genetic Resources, these information systems aim for real worldwide coverage. Unlike other databases, factual data is kept in over 200 clearly defined fields, enabling for more focused database searches[8].Cattle genetics Cattle genetics Cattle genetics Cattle

genetics Cattle genetics Ca Despite their total infertility, taurine cattle and zebu are traditionally regarded distinct animals. A comparison of the mitochondrial DNA of taurine and indicine cattle was one of the earliest contributions of DNA research to the reconstruction of cow domestication. Separate domestications, based on the separation of their control areas, most likely began about 8000 years BC in Southwestern Asia and the Indus valley, respectively. After the 7th century Arabian conquests, Zebus were most likely introduced into Africa. The finding that African zebus have taurinemtDNA suggests that African zebus are the offspring of zebu bulls and taurine cows (Bradley et al. 1998)[9]. The Y-chromosomal INRA124 microsatellite alleles (Hanotte et al. 2000), satellite DNA polymorphism, and AFLP patterns all correlate with the distribution of taurine, indicine, and mixed phenotypes (Nijman et al. 1999). Microsatellite genotypes enabled zebu migratory pathways to be reconstructed (Hanotte et al. 2002)[10]. The tsetse resistance of the native taurine breeds in West Africa prevents zebu introgression (Freeman et al. 2004, 2006b; Ibeagha-Awemu et al. 2004)[11]. Cattle were transported over from Spain and Portugal after the European discovery of America in 1492. Because of their adaptability to hot and arid circumstances, Indian zebu cattle were later transported to Central and South America. The Brahman zebu breed has taurinemtDNA, while the Brazilian Nellore and Gir have both taurine and indicine haplotypes. This is because mostly males were imported and crossed with Creole cattle. Domestic cattle in Southeast Asia and Indonesia are believed to have originated from a cross between zebu and Bali cattle, a domestic version of the banteng.

A demic spread of agriculture from southeastern to northern Europe is supported by autosomal proteins polymorphisms, microsatellite data, and AFLP fingerprinting. The connections between genetic and geographical distances for Mediterranean and Northern breeds are distinct; this is thought to represent independent Neolithic migrations between the Mediterranean coastlines and the Danube. A bigger collection of microsatellite data does show a distinct location for Mediterranean cattle, but it also separates transalpine cattle into two distinct breed clusters: Central-European and Northern European. AFLP data also revealed a distinct location for Central-European cattle. Surprisingly, the Northern-European cluster mainly corresponds to a high variety of milk protein genes, the distribution of human lactase persistence alleles, and Neolithic cow husbandry locations. This led to the hypothesis of cow and human gene-culture co-evolution.

- **Yak**

Yaks are a kind of bovine that may cross with taurine and zebu cattle to generate viable females but infertile males. It is a rare livestock species found in western China's Qinghai-Tibetan Plateau, Mongolian and Russian steppes, and other Himalayan nations. The yak's molecular markers and genetic studies are in the early stages of development. Both haplotypes were identified in a single, tiny wild yak population, indicating that domestic Chinese yaks are descended from a single wild gene pool. In Qinghai and Tibet, a domestication event was believed to have occurred in the early Holocene, approximately 10 000 years before present (YBP). There was no discernible pattern of phylogeographical distribution of main clades in Chinese yak samples collected from various locations in south-western and north-western China. An examination of domestic yak samples from all yak-keeping nations, including China, Bhutan, Nepal, India, Pakistan, Kyrgyzstan, Mongolia, and Russia, discovered a third, less common haplogroup. A single domestication on the Eastern Qinghai-Tibetan Plateau was followed by a westward migration through the Himalayan and Kunlun mountain ranges, and a northward migration through the South Gobi and Gobi Altai mountains to Mongolia and Siberia, according to geographic clines in haplogroup diversity.Mongolia's Gobi Altai, south Gobi, and north Hangai communities, as well as Mongolia's Hovsgol and Russia's Buryatia people, are closely connected. As a result, these populations should be treated as separate genetic units for conservation and fertility purposes. The study of paternal lineages is now possible because to

cross-species multiplication of bovine Y-chromosome unique markers. A full yak mtDNA genome sequence, as well as numerous bovine SNPs that are also polymorphic in yak, will help researchers fully appreciate the genetic makeup of yak populations.

- **Water Buffalo**

Domesticated water buffalo The Indus and Yangtze valley empires are believed to have cultivated Bubalusbubalis. Based on physical, behavioral, and geographic characteristics, water buffalo have traditionally been classified into swamp and river buffalo. River and swamp buffalo will indeed mate if they are raised together from calfhood, and although first-generation hybrids are fertile, it is unknown if fertility will be maintained in future generations. Bubalusbubalisbubalis and Bubalusbubaliscarabenesis are two distinct subspecies of Bubalusbubalisbubalis. River buffalo are more morphologically similar to wild buffalo than swamp buffalo. Swamp buffalo may be found around Southeast Asia as well as China. Although certain regional communities have local names but have been proven to vary in appearance and environmental adaptability, there are no recognized breeds (Chen &Zu 2004). The Indian subcontinent, as well as Southwestern Asia and the Mediterranean nations, are home to river buffalo. In Africa, South America, and Australia, buffalo have just lately been imported.In East India and Bangladesh, the geographical habitats of river and swamp buffalo overlap. Although Sri Lankan buffalo resemble swamp buffalo in appearance, studies of chromosomal number, microsatellites, and mtDNA reveal that they are river buffalo. The genetic difference between river and swamp communities is on par with that between well-known breeds of these other domestic animals.

- **Sheep**

Sheep are one of the oldest pastoral animals, having been domesticated in Southwestern Asia. Relationships with ancestral species have been explored using mtDNA data, as has been done with other domesticated animals. Two haplogroups A and B were discovered, both of which were distinct from sequences found in any current Ovis species. Haplogroup B is carried by the European mouflon, although it is a wild version of early European domesticates. Sheep are most likely descended from one or more Asiatic mouflons. A number of studies have looked at the geographical distribution of haplotypes. Although Haplotype C is uncommon, it has been discovered in Portugal, Turkey, the Caucasus, and China. Haplotype D is linked to the A haplotype and is found in Rumanian Karachai and Caucasian animals. Haplotype E, which lies halfway between A and C, is similarly uncommon, having been discovered in just two Turkish animals. But even though the sheep haplogroup divergence is less severe than the taurine–zebu split, this mtDNA diversity with different haplogroups is similar to what's out there in goats and cattle. In addition, unlike taurine cow haplotypes, the sheep haplogroup has no correlation with regional origin. Distinct maternal lineages in the predomestic population may represent various areas of origin, but another apparent option is the coexistence of several maternal descendants.Another instructive retrovirus copies can be found in most other European breeds, indicating that wool-producing sheep arrived later. This research also discovered a genetic connection between English Jacob sheep and Asian or African people. Although many organizations have investigated the variety of sheep as indicated by microsatellites, little information into the connection between breeds has been gained.

- **Pigs**

By tracking mtDNA, molecular data has given insight on pig domestication. Initial mtDNA analyses indicated that European and Chinese pigs were domesticated separately from European and Asian wild boar subspecies, but subsequent research found that at least seven domesticated episodes took place throughout Eurasia and East Asia. These investigations also indicated that Asian domestic pigs were introduced into certain European breeds in the 18th and 19th centuries.

Demonstrated that domestic pigs of Near Eastern lineage were brought into Europe during the Neolithic period, as well as the domestication of the European wild boar. Once domesticated, European pigs quickly displaced imported domestic pigs from the Near East throughout Europe.Wild and domestic populations were discovered to be linked in both areas. Southwest Asian, African, and American pigs were most closely linked to the Population using all three marker types, while East-Asian mtDNA and Y-chromosomal haplotypes were found in East-African and Nicaraguan groups. Mixed European-Asian origins may be found in Anglo-Saxon, African native pigs, and particularly international breeds.

DISCUSSION

The foundation for future breeding programs is genetic diversity in characteristics of interest. Within a species, genetic variations across individuals, families, and populations show variation. Within the past century, there has been a clear loss of these genetic resources across all farm animal species. Efforts to conserve genetic resources have been countering the loss of genetic resources during the past two decades. As a consequence, significant progress has been made on two fronts. For starters, there is an increasing quantity of data about cattle breeds and their environments that has been carefully gathered. Second, numerous breeds in most livestock species have been subjected to DNA studies. As a consequence, many papers have been produced, ranging from descriptions of local populations to more systematic analyses of worldwide diversification trends. Both phenotypic and molecular findings are available in databases, with the ultimate goal of providing an integrated platform for scientific analysis and decision-making. The present condition of the databases, on the other hand, leaves a lot to be desired. Furthermore, phenotypic data recording and molecular genotyping, while valuable in their own right, must nonetheless converge on consistent and reasonable conservation values for particular breeds.

CONCLUSION

The molecular project-specific databases mentioned in this article have out-of-date information. Database updates, both primary and project-specific, are often overlooked. A second issue resulting from the presence of many project-specific databases is that searches across projects are not feasible since each database has its own design and therefore distinct report formats and export capabilities. As a result, combining data from several databases is time-consuming. This issue may be solved by keeping all data in a single database or by establishing a database search engine that can perform searches across many databases. This is only possible if the project-specific databases meet certain structural criteria that the scientific community must decide on and follow while creating them. This system, which provides search results from a variety of different databases, has been successfully deployed for plant genetic resources on a national basis. New technologies like as high-throughput SNP typing or even whole-genome sequencing are expected to change our knowledge of breed variety and uniqueness in the near future, with the ultimate goal of learning more about the genetic foundation of functional variation.

ABSTRACT

Climate change and variability may affect the incidence of food safety risks at different levels of the food chain, from basic production through consumption. Changes in temperature and precipitation patterns, increasing frequency and severity of severe weather events, ocean warming and acidification, and changes in pollutants' transport routes are just a few of the ways climate-related variables may affect food safety. Climate change may have an impact on socio-economic elements of food systems including agriculture, animal production, global commerce, demography, and human behavior, all of which have an impact on food safety. This article examines the possible effects of projected climate change on food contamination and food safety at different levels of the food chain, as well as adaptation methods and research priorities for dealing with climate change's food safety consequences. In order to better understand the changing food safety situation and create and execute adaptation strategies to address growing hazards linked with climate change, the study suggests that intersect oral and international collaboration is required.

KEYWORDS: *Climate Change, Food Control, Food Safety, Microbiological Contamination, Plant Health.*

1. INTRODUCTION

A number of variables, including global commerce, socioeconomic and technical growth, urbanization, and agricultural land usage, influence food safety.Climate change and variability are only two of the many variables that may alter the type and incidence of food safety risks. Climate change may have direct and indirect effects on the incidence of these risks at different

levels of the food chain, from primary production through consumption[1].Changes in temperature and precipitation patterns, increasing frequency and severity of extreme weather events, ocean warming and acidification, and changes in the transport routes of complex pollutants are just a few of the ways climate-related variables may affect food safety[2].

Temperature rises and variations in rainfall patterns have an effect on the persistence and patterns of occurrence of bacteria, viruses, parasites, and fungus, as well as the patterns of foodborne illness outbreaks. Changes in microbial ecology and growth, plant and animal physiology, and host susceptibility may result in the emergence, redistribution, and changes in the incidence and intensity of plant and animal diseases and pest infestations, all of which may have an impact on foodborne diseases and zoonosis. Climate change and variability, in this context, represent a threat to pest and disease management methods such as Good Agriculture and Good Veterinary Practices, potentially resulting in chemical residues in the food chain[3].

Pathogens, chemicals, and other dangerous substances originating from sewage, agriculture, and industrial settings may contaminate soil, agricultural areas, water, food, and animal feed because of extreme weather events such as floods and droughts. Water and food cleanliness are particularly important in emergency circumstances after natural catastrophes.The biochemical characteristics of water, as well as water microbiology, fisheries distribution, fish metabolic rates, and persistence and patterns of fish, are all affected by ocean warming, climate change-related acidity, and changes in ocean salinity and precipitation.Pathogenic vibrios, harmful algal blooms, and chemical contaminants have been found in fish and shellfish. Climate change and variability may affect other underlying drivers of food safety, such as agriculture, crop production and plant health, animal production and animal health, fisheries, aquaculture, food trade, food and feed manufacturing, processing and handling, and consumer behavior, in addition to the relatively direct impacts of climate change on food contamination and foodborne diseases. These effects have far-reaching public health, economic, social, and environmental implications. A better understanding of all the changes that may occur because of climate change and variability is the first step toward ensuring preparedness for emerging food risks[4]–[9].

1.1 Climate change and food safety impacts:

Because there are so many unknowns, the connections between climate change and fluctuation and food contamination, food safety, and foodborne illnesses are very complicated. This section examines the effects of climate change on food microbiological and chemical contamination, as well as related foodborne illnesses, including the possible effects of climate change on bio toxins such as marine toxins and mycotoxins production and contamination.

1.1.1 Microbiological food contamination and associated foodborne diseases:

Climate change has the potential to affect all three components of the epidemiologic triad (host, agent, and environment).

Climate change impact:

- The transmission sources and modalities.
- Pathogen development and survival in the environment, as well as microbial ecology.
- Among other things, the food matrix.

1.1.1.1 Diarrhoeal symptoms and climate factors:

Diarrhoea is one of the most common causes of illness worldwide, and it is climate-sensitive, with significant seasonal changes. In Peru, higher temperatures were shown to be significantly linked to an increase in diarrhoeal illness episodes in adults and children, with diarrhoeal complaints increasing by 8% for each degree of temperature rise. There have also been reports of links between climate-related severe weather events and monthly reports of infectious water-borne illness epidemics across the globe. Following floods, populations with inadequate sanitation infrastructure and high infectious disease loads can suffer an upsurge in diarrhoeal illnesses such as cholera, cryptosporidiosis, and typhoid fever[10].

Following flooding events, increases in waterborne and foodborne diarrhoeal illness have been recorded in India, Brazil, Bangladesh, Mozambique, and the United States, and are expected in Mexico and Taiwan. The number of instances of gastroenteritis linked with rising temperatures in Australia was predicted to increase dramatically over the next century, according to a climate change scenario research.Salmonellosis, campylobacteriosis, vibriosis, listeriosis, various bacterial infections, parasite infections, and viral diarrhoeal syndromes are among the foodborne diarrhoeal illnesses that have been highlighted as a priority for more regular surveillance because of changing climatic conditions.

1.1.1.2 Bacterial pollutants and foodborne illnesses:

Climate change has the potential to affect all foodborne pathogens and illnesses linked with them (ECDC, 2007). In Europe, Canada, and Australia, time series analysis research on the effects of climate change on foodborne illnesses have mostly focused on salmonellosis and campylobacteriosis.

- **Salmonellosis:**

In average, incidences of salmonellosis rose by 5–10 percent with each one-degree rise in weekly temperature, for ambient temperatures over approximately 5 C, according to a time series analysis research on human salmonellosis in various European countries. Because of climate change, increases in the incidence of salmonellosis of approximately 2% are anticipated in Ireland in the next decades. In Canada and Australia, a link between rising temperatures and salmonellosis outbreaks has also been discovered.According to a climate change scenario research conducted in Australia that projected results until 2100, the number of cases of gastroenteritis would grow over the next century owing to an increase in cases caused by Salmonella and other bacteria. In places like Adelaide, a 1 degree Celsius increase in weekly mean maximum temperatures may result in 7% more Salmonella illnesses. Temperature has a consistent impact on Salmonella throughout a wide variety of nations and locations.

When compared to infections produced by Salmonella Typhimurium, infections generated by Salmonella Enteritidis seem to be more sensitive to the effects of ambient temperature. There seems to be a link between an increase in human salmonellosis and an increase in temperature in the week leading up to the disease's start, suggesting that improper storage temperature and food handling may be significant contributors in the disease's transmission.

- **Campylobacteriosis:**

The Climate Change and Adaptation Strategies for Human Health Time Series Analysis research looked at the effects of weather and climate change on campylobacteriosis in 15 European, Canadian, Australian, and New Zealand nations. Campylobacter infection peaks in most European nations in early spring (April or May), although not all countries follow this trend. The peak is in late June–early July in Canada. In comparison to New Zealand, seasonality is less

apparent in Australian cities. Seasonal trends may vary depending on where you are in the country.

The impact of climate-related variables such as short-term temperature increases on human campylobacteriosis is unknown. Despite the apparent link between temperature and campylobacteriosis, time series investigations have shown that the impact is limited to temperatures between 5 and 10–15 C, which corresponds to the spring months. In contrast to the significant connection found between ambient temperature and Salmonella transmission, Skelly and Weinstein (2003) revealed that the link between higher ambient temperature and increased likelihood of Campylobacter transmission is at best modest. However, a recent Irish research projected a 3% rise in the prevalence of campylobacteriosis because of climate change in the future decades. Weather may influence a variety of possible transmission pathways for campylobacteriosis (water sources, avian activity, fly activity, and recreational contact).Clearly, further research is required to determine the effect of climate on Campylobacter transmission to people.

- **Vibriosis:**

Higher temperatures, sea level rise, severe precipitation, floods, and changes may influence water microflora, particularly pathogenic Vibrio spp., in water salinity. Warming of the ocean and changes in salinity have been shown to affect aquatic microorganisms like Vibrio vulnificus and Vibrio parahaemolyticus, important human pathogens typically transmitted through the consumption of molluscan shellfish harvested from warm southern estuarine waters along the US Gulf Coast. The consumption of oysters collected from northern seas related to higher mean water temperatures has resulted in a major change from occasional instances of V. parahaemolyticus to widespread outbreaks during the past 15 years. Over the past decade, a new V. parahaemolyticus serovar (O3:K6) has developed and expanded quickly across the globe, becoming pandemic in scope. Even though a clear link to global climate change has yet to be established, such fast alterations in the epidemiology of V. parahaemolyticus infection are noteworthy. Vulnificus, infection's worldwide epidemiology has also altered. For example, although most outbreaks are rare, a 1996 epidemic of wound infection and bacteraemia in Israel linked to a single isolate is noteworthy. This biotype of V. vulnificus seems to be a highly virulent hybrid that had been prevalent in brackish environments for years to decades before producing illness in 1996.

It was believed that variations in inland fish farm water temperatures aided the organism's development, increasing the risk of infection in people handling or eating fish produced in these waters. Following that, a time series study of air temperatures for the two decades covering 1980–1999 showed a statistically significant rise in summer temperatures, which peaked around the same time the organism was linked to human illness. While not conclusive, this data indicates that global climate change had a role in the development of this strain.

The greatest model for understanding the potential for climate-induced alterations in enteric pathogen transmission is Vibrio cholerae. Although modest amounts of the bacterium may be isolated from estuary waters all over the globe, the illness is only seen in a few places (mainly the tropics and subtropics). There are distinct epidemic peaks (which are often seasonal) followed by periods of relative quiet in certain regions. Cholera endemicity is thought to be caused by a complex interaction of environmental and biological variables. Temperature, salinity, iron content, and sunshine are all abiotic (environmental) variables that affect V. cholera toxin production as well as phytoplankton and zooplankton populations. The survival and growth of V. cholerae in the estuarine environment are influenced by a complex series of interactions. Although this is a simplified summary, it should be clear that even minor changes in these critical environmental factors, which are likely to occur as a result of climate change, can have

significant implications for cholera transmission, with the developing world bearing the brunt of the public health consequences. This is backed by a recent research that found that temperature and rainfall may help explain seasonal variations in the number of cholera cases in Bangladesh. The first and second peaks of infection seemed to be caused by low and heavy rainfall, respectively, whereas the winter trough was explained by low temperature

- **Other bacterial foodborne illnesses:**

Global climate change may have an effect on other bacterial causes of foodborne illness. Because many, if not all, foodborne bacterial pathogens may develop at room temperature, with quicker growth favored at higher temperatures, changes in ambient temperatures may also hasten pathogen proliferation throughout the production to consumption continuum, assuming all other variables stay constant. Enteric infections such as Clostridium, Vibrio, and Aeromonas spp. cause gastroenteritis, which seems to peak in the summer or have a positive connection with ambient temperature. Recent research in the United Kingdom, however, casts doubt on the role of temperature and climate change in the increasing frequency of these foodborne diseases in England and Wales.

1.2 Other zoonoses, animal health and veterinary public health issues affected by climatic factors:

One of the many variables driving the emergence and spread of animal illnesses, as well as the transmission of zoonotic infections from animals to humans is climate change. Other variables include ecosystem variety, function, and resilience, as well as changes in the livestock industry's organization, breeding, and husbandry cattle and animal products, as well as in international commerce. These elements are not mutually exclusive.Climate change has an impact on each of them.

1.2.1 Climate change and emerging zoonosis:

Climate-related modifications in protection against pathogenicity in the habitat, changes in migratory routes, carriers and vector, and shifts in forest environment may all raise the likelihood of developing zoonosis. Rift Valley fever, West Nile fever, tick-borne diseases, and non-zoonotic disease vectors like Blue tongue, African Horse Sickness, and African swine fever are examples of zoonotic and non-zoonotic illnesses whose proportion will be deeply affected by climate adaptation strategies and fluctuation.

1.2.2 Climate change impacts on animal health and veterinary publichealth: potential pathways:

Climate change may have an impact on animal health and veterinary public health issues in the following ways:

- An increase in animal illness susceptibility.
- An increase in the range or abundance of vectors/animal reservoirs, as well as the lengthening of vector transmission cycles.
- Climate change's impact on farming/husbandry practices (including the use of veterinary drugs).

1.2.2.1 Increase in animal susceptibility to disease:

Climate change may have a direct or indirect impact on animal disease susceptibility. Climate change influences animals' living circumstances, which may lead to parasite illnesses (such as worm infestation/affection and taenia), nutritional problems, sunstroke, and dehydration. Extreme cold, droughts, excessive humidity, or heat can predispose cattle to complex bacterial syndromes like mastitis, which may necessitate antibiotic treatment.Because their metabolic processes are affected by water temperature, salinity, and oxygen levels and their habitats are fragile, aquatic creatures are especially susceptible to climate change. Fish, especially shellfish, react to changes in their biological environment (predators, species interactions, and illness) as well as climatic fluctuations. A warmer climate is anticipated to cause difficulties in the aquaculture industry, such as increased disease susceptibility, especially in intensive systems.

1.2.2.2 Increase in the range or abundance of vectors/animal reservoirs and prolonging the transmission cycles of vectors:

Climate science ecological changes, such as fluctuations in precipitation and warmth, may substantially affect the range, periodicity, and occurrence of many pathogenic and vector-borne illnesses, due to the sensitivity of the vectors and animal hosts from these diseases to climatic variables. Climate warming will have a significant impact on vector-borne and rodent-borne illnesses, as well as animal micro parasites, and may lead to novel transmit modes and host species alterations.

Fast developing opportunistic agents, conveyed by rapidly reproduced, highly mobile, and habitat generalist vectors, are expected to be vector-borne diseases that react most quickly to climate change. Takeover by exotic vector-borne viral illness will be especially dangerous for temperate nations.

1.2.2.3 Impact of climate change on farming/husbandry practices:

The effect of increasing heats on agricultural practices and the reactions to them are expected to vary across the globe. Heat-resistant livestock breeds may be utilized, although this modification could increase vulnerability to diseases. More livestock may be brought inside in certain regions in order to escape heat and stress, increasing the spreading of infection. Higher temperatures, on the other hand, may lengthen the grass-growing season in certain regions, allowing for more widespread cattle grazing and increased exposure to vectors and animals, according to the FAO.

Modifications in livestock breeding methods (e.g., intermingling or cramming of food - producing animals) in reaction to natural disasters or climate-related changes may enhance disease transmission, resulting in higher pathogen loads in faces and increased corpse contaminants. Increased usage of veterinary medicines owing to the spread of animal illnesses because of climate-related changes may lead to higher and perhaps inappropriate amounts of animal source in animal sources. This may have ramifications for public health and commerce.

2. DISCUSSION

The author has discussed about theClimate Change and Food Safety,Changes in temperature and precipitation patterns, increasing frequency and severity of extreme weather events, ocean warming and acidification, and changes in the transport routes of complex pollutants are just a few of the ways climate-related variables may affect food safety. Temperature rises and variations in rainfall patterns have an effect on the persistence and patterns of occurrence of bacteria, viruses, parasites, and fungus, as well as the patterns of foodborne illness outbreaks. Changes in microbial ecology and growth, plant and animal physiology, and host susceptibility may result in the emergence, redistribution, and changes in the incidence and intensity of plant and animal diseases and pest infestations, all of which may have an impact on foodborne

diseases and zoonosis.The Climate Change and Adaptation Strategies for Human Health Time Series Analysis research looked at the effects of weather and climate change on campylobacteriosis in 15 European, Canadian, Australian, and New Zealand nations.

3. CONCLUSION

The author has concluded about the climate changes and the food safety,Food safety concerns may be affected by climate change and fluctuation at many stages of the food chain, from fundamental production through consumption. Climate-related factors may impact food safety in a variety of ways, including changes in temperature and precipitation patterns, increased frequency and intensity of extreme weather events, ocean warming and acidification, and changes in pollutant transport pathways, to name a few. Agriculture, animal production, worldwide commerce, demography, and human behavior, all of which have an effect on food safety, may be affected by climate change. The impacts of predicted climate change on food contamination and food safety at various stages of the food chain are examined in this article, as well as adaptation strategies and research objectives for coping with climate change's food safety repercussions. The research indicates that intersectoral and worldwide cooperation is needed to better understand the changing food safety situation and to develop and implement adaptation measures to meet increasing risks related to climate change.

A LOOK AT THE SOCIAL-MORAL, PHILOSOPHICAL CONCEPTS IN THE WORLD OF SHAKESPEARE AND IN HIS WORK

Shodiev Shahobiddin Sharofiddinovich*

*Teacher,
Department of Foreign Languages,
Bukhara State Medical Institute,
UZBEKISTAN

ABSTRACT

The article analyzes the socio-ethical and philosophical concepts of Shakespeare's period and his work, the connection of his works with ancient literature and Oriental art of speech, the scope of ideas and themes put forward in his dramas. It also discusses the situation in which Eastern philosophy is in harmony with Western culture, individual freedom, and social inequality.

KEYWORDS:*Drama, Social Inequality, Social Thinking, Enlightenment, Pathos, Emotion, Observation, Culture, Lust, Morality.*

INTRODUCTION

Three factors played a decisive role in the development of medieval literature. These are folk art, ancient culture and art, and the influence of the church. In particular, the role of folk poetry traditions is fragmentary. Labor songs, which are the oldest examples of poetry, went beyond customs and rituals in the middle Ages and formed as an independent literary genre. Although religious superstition and bigotry prevailed for a long time, it still did not quench people's natural desire for the blessings and joys of life.

The influence of ancient culture on medieval literature is reflected in Shakespeare's King Lear, Macbeth, Hamlet, Timon of Athens, Anthony and Cleopatra, Julius Caesar, Richard III, Richard II, and Henry IV. , Henry V, and King John.

In the development of English drama, the first examples of the literature of this nation appeared in the form of songs dedicated to the issues of labor, war, domestic life. Such songs, which embodied special events in the life of the people, became the basis for the creation of epic epics. In turn, they reflect the people's daily life, life mixed with joy and sorrow, dreams, hopes for the future, happiness, prosperity. In Shakespeare's dramas, positive heroes (Hamlet, Hortsio, Laert, Duncan, Banko, Macbeth, McDuff, and Lennox Seward) are embodied as brave, courageous, healthy, generous, always ready to help the oppressed, to sacrifice their lives for the motherland.

For example, in the world-famous "Romeo and Juliet", love is glorified as a high divine feeling. The brave, courageous Romeo, who sacrificed in the way of his love, is honored. In contrast, the

actions of cowards, traitors, unproven, ruthless, ambitious people (Claudius, Gertrude, Polonius, Macbeth, and Lady Macbeth) are ruthlessly exposed.

The play is characterized by the expression of events in folk epics, the courage of the noble Romeo, as well as the analysis of deep human feelings, qualities, friendship, devotion, which enhances the value of this artistic monument.

In turn, the drama "Romeo and Juletta" stands out among the monuments of art. Elements of realism and populism are reflected in the image and interpretation of positive images. The similarities between this work and AlisherNavoi's epic "Layli and Majnun" and the Uzbek people's epic "Tahir and Zuhra" can be seen in the character, intensity, power and aspirations of the heroes of both works. Both Romeo and Majnun are tragically killed because of the disagreement between the people, the conflict between them. At the end of the work, the conflict between the two tribes and two families at the top of the graves of the lovers ends. Romeo is shown in a highly dramatic pathos that Farhod is the victim of a lie.

The love, joy, devotion and betrayal sung in Shakespeare's works are the main themes of the playwright's work. They emphasize the psychology of the heroes. Among Shakespeare's plays, Romeo and Juletta stand out. It depicts human love and worldly events, and love is sung as a result of man's natural feelings. In the work of the playwright there are features of Eastern literature, such as the praise of beauty, the pleasures of life, the thoughtful inspection of life. In works that depict the evolution of human psychology in his heart, the protagonists make accusations against the period.

Literature, in fact, means the ascension from the nafs to the heart, from the heart to the soul, from the soul to the mystery, from it to the meaning and essence. In each of these "statuses" the talented writer sees the human personality in a new light and laughs at new changes. Shakespeare has achieved all this. Literary scholar I. Hakkulov emphasizes that one of the most attractive features of Shakespeare's drama is to show the true image of man in the "mirror" of emotions, to describe the struggles of desire and destiny in the language of the situation.

When thinking about literary influence, it is impossible not to remember Dante. The influence of Oriental literature on Dante's work was specially studied by N.Kamilov.

Dante's work was strongly influenced by Eastern literature. After the Me'rojnama and the Thousand and One Nights were translated into Spanish on the orders of King Alfonso X, various legends about the Prophet Muhammad's Meroj, Eastern poetry, played a major role in the development of secular European literature.

All this is not in vain.Because the influence in all areas was also strong in the literature department. It is acknowledged that the prose examples of Eastern word art in terms of etiquette and teaching had a great influence on European literature.

Panchatantra, written in Sanskrit in the 3rd and 4th centuries, had a strong influence on European literature in the middle Ages and the Renaissance in terms of genre, style and content. This collection of short stories, called Kalila and Dimna, was translated into Arabic in the eighth century, and then into Greek, Hebrew, Latin, Spanish, and other languages. Slovak scientist M. Galikakademik S. F. Relying on Oldenburg, he said: “Panchatantra is the second most widely circulated work in the book world after the Bible. He influenced the development of medieval and Renaissance literature to such an extent that it cannot be compared to any other example of Oriental literature.

Indeed, no nation can ever develop in isolation from others, creating its own special culture. The centuries-old cultural ties between East and West, especially the process in the Middle Ages and the Renaissance. Confirms the idea of happiness.

The homeland of the Renaissance movement is Italy. When we talk about the Renaissance, we should first focus on the main aspects of the literature of this country. One of the greatest masters of speech in the cultural development of mankind is Dante Alighieri.

The work that sealed Dante's name in eternity, The Divine Comedy, consists of 33 songs (poems). This epic is further divided into parts such as "Hell", "Araf" and "Paradise", which describe the three parts of the world. The songs are written in the form of tertsina, i.e. trinity.

Dante used allegory and symbolism in the medieval genre of "vision" to create the Divine Comedy. However, the plot of "Dorulbaqo" reflects not only religious views, but also important issues related to real life. The protagonist of this work is the author Dante himself, and the epic tells the story of his birth while alive, crossing the borders of the eternal world under the guidance of the spirits of the ancient Roman poet Virgil and his lover Beatrice. it consists of a nine-story depth. Sinful spirits suffer on those floors.The lower the rank, the heavier the punishment.

Dante, the first representative of the new age, in the fourth song of "Hell", the poet embodied great people who made an invaluable contribution to the development of science, art and literature. The traveling poet meets Eastern scholars, such as Homer, Aeschylus, Sophocles, Aristotle, Plato, Socrates, Pythagoras, Heraclitus, Democritus, as well as our great ancestor Ibn Sina. The next stage of the eternal world is described in the second part of the epic "A'raf", which is located opposite the globe. The ocean separates it from the ground. There is a high mountain on the island in the middle of the ocean. The mountain has seven steps, and as it passes over them, the rebellious slaves are cleansed of sins.

During the Renaissance, genius writers also flourished in Spanish, French, and English literature. Miguel Cervantes, author of Don Quixote, François Rable, author of Gargantua and Pantagruel, great playwrights William Shakespeare, and Christopher Marlowe are proof of our point. Under the influence of the socio-political events that took place in Western Europe in the XV-XVI centuries, advanced humanistic ideas were propagated in the literature due to the peculiarities of their historical development.

In general, one of the main features of Renaissance word art is that it has a realistic content in addition to the humanistic spirit. The creators adopted the ideas of the struggle for equality and justice from ancient sources. Influence on such features of ancient literature can be seen in the works of F. Rable, Cervantes, and many tragedies of Shakespeare and Marlo.

The positive heroes of Renaissance realism embody incomparable courage and bravery. The great humanists who defended the freedom of the individual also reflected the living spirit of the Renaissance by creating noble images who believed in their own power, the triumph of justice, fought for truth, and were pure in heart.

As far as the question of literary influence and connection is concerned, it is necessary to dwell on two contradictory but at the same time interdependent situations. We are talking about synchronous and diachronic effects here.

The Enlightenment did not consider the existing social systems and orders on Earth to be perfect. According to them, the unfavorable situation in society should be corrected or eliminated by the supreme power of man - the intellect, and ignorance should be removed from the mire of backwardness.Because although God created the universe, man has the freedom, the right, and the obligation to control it. That is why human creativity is so highly valued.

Proponents of this line have argued that human enlightenment is capable of leading the world to goodness, arguing that there is a harmony between "sociality" and "naturalness," "civilization," and "nature." Therefore, in the literature of this period, in general, in the arts in general,

emphasis was placed on strengthening the material basis of culture and enlightenment, and the struggle of the human child with the forces of nature and its victory in this process, the test of human thinking.

The importance of the main aesthetic views in the Enlightenment literature is explained by the fact that the educational features of art were directed to the reconstruction of society. The fact that the writers of the English Renaissance created political-philosophical novels, philosophical stories, dramatic works of political-moral content in the spirit of enlightenment confirms our opinion. Enlightenment writers saw literature as a tool of ideological struggle. They sought to exaggerate the courage, hard work and initiative of their positive heroes, as well as the idea of generosity. These features can be observed in the activities of major artists from different countries.

The Enlightenment opposed conditionality, artificiality, in the literature of classicism, and, unlike the classicists, appealed to the lives of ordinary people. Their innovation in literature was also evident not only in the expression of new ideas, but also in the expression of new forms. The enlighteners gave the existing shamails a unique look and a unique meaning. In particular, they raised the development of drama to a new level. Thus the demands of classicist drama on the higher (tragedy) and lower (comedy) genres were deviated from.

Representatives of this direction paid special attention to the description and analysis of the daily concerns and aspirations of the people. These qualities were vividly reflected in Shakespeare's work.

It is in the development of the novel and prose in general that a great step has been taken in the literature on theoretical and aesthetic issues due to the Enlightenment movement. New forms of epic genres appeared in fiction - educational-didactic novels, domestic novels, philosophical short stories, comic epics, etc., and thus unique methods of analysis of the human psyche were discovered.

Speaking of the great representatives of Enlightenment literature in Britain, it is worth mentioning the names of famous novelists of this country Daniel Defoe, Samuel Richardson, Henry Fielding, Tobayas George Smollett, Richard Brinsley Sheridan, poet Robert Byrns. In particular, Defoe enriched the treasury of world literature with his works about the traveler Robinson Crusoe. In the first of this series of novels, the writer tells of a man who landed on a deserted island and survived because of his mind, will, ingenuity, aspirations and hard work. , skillfully described his struggle for survival.

In general, this immortal work alone is enough for the great writer to take an eternal place in the history of world literature. Defoe, who introduced the novel genre into English literature and was one of the leading intellectuals of his time, was also well known as a publicist and researcher. His scientific, creative and literary activity is wide and varied. In addition to his numerous articles and pamphlets, the author has a number of works on philosophy, economics, history, pedagogy, statistics, geography, and medicine.

As a progressive writer of his time, Defoe Robinson Crusoe was able to incorporate both the most delicate emotions, qualities, and conflicting traits of the human child into his character. The longevity of the work can be explained by the fact that the breath of labor that changes nature and society is in the depths of the inscriptions.

After this work, written in 1719, Defoe wrote The Life and Adventures of the famous Captain Singleton, as well as a sequel to Robinson Crusoe's past.

"The Adventures of Robinson Crusoe" was translated into Uzbek by YuldashShamsharov.

The work of Jonathan Swift, a contemporary of Defoe, also plays an important role in English literature of the Enlightenment. He is one of the most famous critics in the history of not only English but also world literature. Swift's life and literary work cannot be imagined without turning a blind eye to the various political struggles of his time, the social realities of his native Ireland. The writer, who put the happiness of the people and the happiness of the homeland above the narrow interests of the ruling circles, took an active part in the struggle against the oppression of British colonialism, along with his patriotic colleagues for the freedom of the Irish people and country.

Although the play depicts mythical, fairy-tale-like events, it is primarily about human relationships, the intricacies of social life, political hypocrisy, and the ignorant real face of society. It ridiculed the ugly deeds and foolish customs of the rulers and those around them. This novel, which reflects the characteristics of the period, is a true generalization of English life, a critical and objective assessment of it, and a reflection of the writer's attitude to the politics, science and culture of the time.

In turn, the Enlightenment movement has produced such great artists in England as Shakespeare, John Lily, Robert Green, and Thomas Nash, famous for their socio-political, philosophical and literary activities. While the English Enlightenment developed in the post-revolutionary period and took a compromise with it, the movement's supporters in France emerged at a time when the struggle of the social forces against the monopoly feudal order was intensifying and strengthened, with the ultimate goal of preparing a bourgeois revolution.

Dramaturgy plays an important role in the literary heritage of the great enlightener Shakespeare. During his short life, he managed to write 37 dramas and further enriched the treasury of world literature with his immortal works. He had a special love for theater and was engaged in drama writing for fifty-three years of his life. We have inherited such masterpieces as King Lear, Macbeth, Hamlet, Othello, Corliolan, Julius Caesar, Anthony and Cleopatra.

The idea of the great French thinker Victor Hugo Voltaire's great influence on the culture of the time: "He was more than a man" can also be applied to Shakespeare.

The role of Shakespeare’s work in the success of English drama in the Renaissance is fragmentary. One of the greatest playwrights in world literature, he was famous for his plays "King Lear Barber", "Hamlet" and "Othello". In these works, the author praised human intelligence, business acumen and dexterity. In turn, he ridiculed jealous, lowly, hypocrites like Yago. His dramas also condemned social inequality.

Shakespeare’s ideas had a strong influence on the social thinking and literature of many countries. He is one of those who were able to give a new spirit not only to the literature of the English Renaissance, but also to the classical word art of this people.

The influence of ancient culture on medieval literature is reflected in Shakespeare's King Lear, Macbeth, Hamlet, Timon of Athens, Anthony and Cleopatra, Julius Caesar, Richard III, Richard II, and Henry IV. , Henry V, and King John. In his dramas, positive heroes (Hamlet, Hortsio, Laert, Duncan, Banko, Macbeth, McDuff, and Lennox Sivard) are embodied as brave, courageous, healthy, generous, and always ready to help the oppressed, to sacrifice their lives for the motherland.

In Shakespeare's works, Eastern culture, science, and philosophy were combined with Western culture. The following words of the great literary critic Mikhail Bakhtin in his book "Aesthetics of Words" are noteworthy: Every cultural event lives within boundaries. When a culture is out of bounds, it loses its support, crumbles and dries up, becomes the same, and finally dies ”[1; 266].

The Renaissance paved the way for Enlightenment rhetoric [2; 379]. Let us consider the terminological meaning of this movement. The word "enlightenment" is used in a broad sense in the sense of making the people educated, enlightened, but in a narrow and clear sense it refers to the intellectual movement in the era of the rise of feudalism.

The importance of the main aesthetic views in the Enlightenment literature is explained by the fact that the educational features of art were directed to the reconstruction of society. The fact that the writers of the English Renaissance created political-philosophical novels, philosophical stories, and dramatic works of political-moral content in the spirit of enlightenment confirms our opinion.

The Enlightenment opposed conditionality, artificiality, in the literature of classicism, and, unlike the classicists, appealed to the lives of ordinary people. Their innovation in literature was also evident not only in the expression of new ideas, but also in the expression of new forms. The enlighteners gave the existing shamails a unique look and a unique meaning. In particular, they raised the development of drama to a new level. Thus, the demands of classicist drama on the higher (tragedy) and lower (comedy) genres were deviated from [3; 467].

Representatives of this direction paid special attention to the description and analysis of the daily concerns and aspirations of the people. These qualities were vividly reflected in Shakespeare's work.

In all his works, Shakespeare promoted the doctrine of the detailed depiction of life in all its intensity and contradiction as the first basis of drama, defended the theoretical principles of realistic theater and drama. The artist also proved that real drama has a wider and more possibilities than the art of painting in depicting life events, human heart and emotions, actions, deeds, characters of people of different social classes. The fate of King Lear is family and children, state and personality.,a wide range of possibilities for continuous reflection on dozens of issues, such as practice and morality, lust and conscience. So is the immortality of a work of art.

It is noteworthy that Shakespeare was a proponent of the simplicity and authenticity of dramaturgy. He raised life issues that were relevant for his time. Feudal-nobility regimes protested the ruling environment. The tragic resolution in these works, written with high pathos, sounded like a sign of sharp protest against the environment of the time.

The pinnacle of Shakespeare's work is undoubtedly Hamlet. The idea of subjugating the powerful forces of nature and the universe to the will of man, studying its laws and serving these mysteries for the benefit of mankind is embodied in the image of Hamlet.

The tragedy shows the clash of two opposing forces: Claudius and Hamlet. One of them is the enlightened, educated; honest, conscientious Hamlet is a symbol of goodness. He struggles with himself first and foremost as a human being. Another powerful force, Claudius, embodied doubt, denial, and destruction.

Shakespeare skillfully instills in the nature and psyche of the protagonist that one of the most important phenomenal phenomena inherent in humanity is the need to think at the heart of everything. While the logic that "people need human morality based on human nature, experience, and understanding" [1; 7] defines Hamlet's worldview, Claudius is ready for any humiliation for glory and the throne.

Shakespeare's dramas focus on beauty, emotion, intuition, observation, and imagination, as opposed to the world of shadows ruled by ideas, to an interesting, full reality. excellent Because the beauty in art is the beauty that is born and re-created in the land of the soul, since the creation

of the soul is higher than nature and its phenomena, the beauty in art is equally superior to the natural beauty ”[4, 72].

In Shakespeare’s dramas, the focus is on beauty, emotion, intuition, observation, and imagination, and appeals to an interesting, full-fledged reality as opposed to the world of shadows ruled by ideas. [5; 72].

According to the Russian thinker Chernyshevsky, it was Belinsky's works such as "Articles on Folk Literature", "Literary Dreams", "The Ball of Wisdom", "Mentsel-Goethe Critic", "Poetry of Mikhail Lermontov", "Hamlet. Shakespeare's Drama ”series showed the real way in the emergence of national literature.

“You just have to write about what you know, what you know, and when you write, be sincere and honest; let the described situation burn the human heart, help to evaluate the reality, become a part of the reality experienced by the reader ”[6; 44]. Hence, Shakespeare’s dramas can answer all of this. Rare works created by the playwright play an important role in the development of literary and aesthetic views of the Renaissance artists, and these works depict life and death, joy and sorrow, happiness and tragedy side by side.

ABSTRACT

The article examines the phenomena of individual sense of justice as an internal determinant of legally significant behavior - lawful or delinquent. A complex of its main components (properties), which are the most significant in the determination of the legal orientation of social behavior, is presented. Their substantive characteristics are stated, reflecting the opposite tendencies - law-abiding and illegal orientation of legal consciousness. The main spheres of legally significant behavior are noted, which cover the content of legal consciousness. Based on the structure of individual legal consciousness, the phenomenology of public legal consciousness is considered as an internal determinant of the rule of law in society and its opposite phenomenon - crime. Attention is paid to the reflection of public legal consciousness in the individual, which has a formative influence and in which one of the mechanisms of integration of individual psychological phenomena into social and psychological ones is manifested. Prospects for applied research of this problem are outlined.

KEYWORDS:*Individual Legal Consciousness, Public Legal Consciousness, Properties Of Legal Consciousness, Content Of Properties Of Legal Consciousness, Defects Of Legal Consciousness.*

INTRODUCTION

Ensuring law and order in society is traditionally considered as the fight against crime and other offenses, which in real practice is focused on identifying illegal acts and bringing the perpetrators to justice, and also includes a list of some measures to prevent offenses. The strategy of preventive activity is based on the principle of eliminating the causes and conditions of illegal acts, since crime is viewed as a secondary phenomenon in relation to other social phenomena that act as its determinants. One of the drawbacks of the study of crime factors, traditional for criminology, is to consider them as being side by side without differentiation in the socio-psychological mechanism of the legal behavior of people, without disclosing the influence of

each factor on the subject of behavior - first of all, on his inner world, which determines the nature of behavior. The disadvantage of the traditional “causal” approach to crime prevention is also related to its one-sidedness. This is expressed in the emphasis on the analysis of the factors of illegal behavior of people, which does not fully cover the factors of the opposite phenomenon - the rule of law. A systematic understanding of the social mechanism of the generation of crime can be achieved only by analyzing an integral phenomenon - the legally significant social behavior of members of society, both offending and lawful.

Based on the provisions of the principles of determinism and consistency, thefactors of law and order (crime) must be considered as a tiered system [see. more details 5] in which the causal determinants that directly affect the state of law and order (crime) are the phenomena that express the inner essence of the subjects of legally significant behavior. The rest of the determinants, which are various kinds of social conditions and influences, are secondary, external. They influence the formation and change of direct, internal determinants. In the theory of law and legal psychology, the concept is used to denote the inner essence of the subjects of legally significant behavior

"Sense of justice".It is applied both in relation to an individual, expressing an individual sense of justice, and in relation to a community of people or a certain social group - public sense of justice.

Characterizing individual legal consciousness in its most general form, it should be noted that it accumulates a set of psychological properties of the individual, manifested in the sphere of consciousness, which determine the legal orientation of the individual's behavior - law-abiding or illegal. Public legal awareness is the integration of the individual legal awareness of members of a community (social group) and at the same time, manifesting itself as a socio-psychological phenomenon, it influences the formation of individual legal awareness of members of society. This influence is due to the fact that a person, being in society, to one degree or another is guided by the opinion of the people around him, their attitude to certain actions, their reaction to these actions and the consequences associated with it. He builds his behavior, showing, on the one hand, independence (self-determination, the desire for personalization), and, on the other hand, conformism (the desire to ensure his own social adaptation and identification with the social environment).

Cognition and description of public legal consciousness, as an integrative education - a socio-psychological phenomenon, is based on the study of the individual legal consciousness of members of society and the systemic generalization of data. This generalization presupposes the establishment of prevailing trends in the qualitative characteristics of the legal consciousness of members of the community, the distribution of their types, as well as the establishment of socio-psychological influences on individual legal consciousness. Such influences are associated with the fact that people tend to assimilate the mentality prevailing in society and be guided by them. Thus, individual legal views are formed not only as a result of a personal assessment of the state of law and order, crime and other components of legal reality, but largely as a result of orientation towards the corresponding views of others. The individual develops ideas about the legal consciousness of other people, first of all, representatives of the social group to which he relates himself and on which he is guided. It assumes what opinion these people have on certain issues of legal reality, what positions they hold and have inclinations in terms of lawful and offensive behavior, what is their relationship to certain illegal acts, to lawful options for solving certain life problems, as well as to actions, aimed at fulfilling a civic duty to ensure law and order (for example, to report unlawful acts and persons committing them to law enforcement agencies, to give accusatory testimony, etc.). These views determine

The formation of individual legal orientations, positions, relationships, socio-legal expectations and personally acceptable ways of acting.Such a subjective picture of public legal consciousness is formed both as a result of the information flow, including communication with people around, and as a result of projection - ascribing to other people their own ideas, attitudes, personal norms of behavior and other properties of their own legal consciousness.

The qualitative characteristic of individual and social legal consciousness can be revealed structurally, which provides for the allocation of the components of an integral legal consciousness, as its properties and reflection of their substantive characteristics. In most scientific works, legal consciousness in its most general form is defined as his knowledge of legal norms, his attitude to these norms and his attitude to the need to comply with them. Individual legal consciousness reflects the legal worldview of a person and includes in its structure those psychological properties of an individual that relate to the phenomenology of consciousness, primarily to the cognitive sphere of the individual. Such properties are knowledge, perceptions, beliefs, expectations, evaluative standards, personal principles and norms, relationships.According to A.R. Ratinov and G.Kh. Efremova, the structure of legal consciousness includes four main types of relations: firstly, attitudes toward law (its principles, institutions and norms), secondly, evaluative attitudes toward the legal behavior of people, thirdly, toward law enforcement agencies and their activities, and, in -fourth, to one's own legal behavior (legal self-assessment) [8]. This point of view has its grounds, but it needs to be concretized. The structure of legal consciousness is determined by the structural-functional approach to understanding the psychological mechanism of legally significant behavior and the role of psychological properties of the individual in it. Thus, in the psychological mechanism of legally significant behavior (lawful or illegal), a mental reflection is manifested: legal norms; legally significant ways that the subject can use; objects to which legally significant behavior is directed; expected results of their actions; the social environment in which the subject acts; legal response measures; oneself as a subject of legally significant behavior.

A comprehensive analysis of the legal consciousness of an individual, the determination of the structure of its elements (properties) requires, on the one hand, the identification of properties that legitimately orientate behavior and provide anti-criminal stability of the individual. On the other hand, it is necessary to establish possible defects in legal consciousness, i.e. those of its properties that are internal prerequisites for illegal behavior. The disclosure of the legitimately orienting content characteristics of legal consciousness (its properties), as well as the characteristics of its criminogenic defects, can be carried out on the basis of an understanding of the criminogenic predisposition of the individual, the essence of which is expressed in the acceptability of certain criminal methods of action (selfish, violent, etc.) to satisfy needs or resolve problem situations. Law-abiding legal awareness consists in a negative attitude towards such methods, in rejection of their use, in resistance against the criminogenic influences of other persons and circumstances of the situation, as well as in the readiness to participate in strengthening the rule of law, including assisting law enforcement agencies in exposing criminals, fulfilling their civic duty.

Based on this approach, and based on the data of empirical research, as well as taking into account the work on this problem [1; 2; 3; 4; 6; 7; ten; 11], it is possible to highlight the main aspects of individual legal consciousness, which are its structural elements. These include the following.

1. Knowledge of legal regulations defining obligations, prohibitions, the procedure for the implementation of legitimate interests. Lack of sufficient legal knowledge is a prerequisite for offenses.

2. Relationship to legal regulations. It can be positive, negative, contradictory, and have different meaningful shades.

3. Attitudes towards legitimate ways to meet needs or resolve problem situations: work on a legal basis; to search for compromises in conflict; resorting to lawful means of protecting personal interests, etc.

1. Ideas about a law-abiding person and attitude towards him.

2. Attitude towards illegal ways of satisfying personal interests (selfish, violent, etc.).

3. Ideas about a person committing a wrongful act(of a certain nature) and attitude towards it

4. Attitude towards law-protected social values. This attitude can be respectful, humane or selfish, consumerist, dismissive, hostile. Respect for social values significantly determines the choice of legitimate and morally approved ways of interacting with them. The opposite attitude does not directly predetermine the subject's propensity for harmful actions, but is typical for persons committing illegal encroachments on them.

5. Ideas about the legal positions of other people. The subject of social behavior is characterized by an orientation toward other people, primarily those with whom he identifies himself, who for him represent a reference social group.

6. Social and legal expectations, express ideas about the consequences of illegal behavior and the success of legitimate ways to satisfy interests. These expectations relate, on the one hand, to the onset of legal responsibility for committing illegal actions (its inevitability or the ability to avoid), on the other hand, the success of legitimate ways to satisfy certain interests.

7. Attitude towards illegal behavior of other people. In this respect, on the one hand, one's own attitude towards illegal acts is projectively manifested. On the other hand, this attitude acts as the basis of an individual position in fulfilling a civic duty of participation in maintaining law and order.

8. Attitude to law enforcement activities of state bodies, which expresses attitude to legal control of law enforcement agencies, to their detection of illegal acts and the persons committing them, to the application of legal sanctions and measures of legal responsibility, as well as the attitude towards law enforcement officials.

9. Attitude towards the fulfillment of the civic duty of participation in the maintenance of law and order, namely: participation in the protection of law-protected social values, in the suppression of illegal acts, in the exposure of criminals and in justice over them. This attitude is concretized as an attitude towards various forms of participation in the maintenance of law and order, which are a legally established obligation (for example, participation in a criminal process as a witness), or act as a moral civic duty (for example, to prevent illegal actions, report to law enforcement agencies), or organized by state bodies and public institutions (for example, participation in preventive measures or in the protection of public law and order together with employees of the internal affairs bodies).

10. Attitude towards the criminogenic influences of other persons who incline to commit illegal acts. The most important component of legal consciousness is a critical attitude towards such influences, an awareness of one's own responsibility for one's actions, the need for legal self-determination.

Among the elements (properties) of legal consciousness, there are the most significant in the determination of the legal orientation of behavior, which express the most significant differences in the legal consciousness of law-abiding persons and offenders. An empirical study of the

peculiarities of the legal consciousness of juvenile offenders showed that the most significant differences in their legal consciousness are manifested:

1) in ideas: about the positive aspects of illegal methods of action, their commonness in the reference community and in an approving and justifying attitude towards them; about the positive qualities of the subjects of the illegal act and the justifying or sympathetic attitude towards them; about the limited possibilities of legitimate ways to solve certain problems and in an indifferent or skeptical attitude towards them; about such personal qualities and position of a law-abiding person, which determine a sympathetic or indifferently alienated attitude towards him; about the low social and personal significance of the negative consequences of unlawful acts, including responsibility for unlawful behavior; about the predominantly negative qualities of law enforcement officials;

2) in the peculiarities of social and legal expectations: in the confidence in the possibility of avoiding responsibility when committing a wrongful act; in the opinion that a significant part of the perpetrators of crimes avoid responsibility, combined with a positive attitude towards this phenomenon; in superficial ideas about the consequences of criminal punishment, in this connection, it is not recognized as a factor that hinders the achievement of well-being in life;

3) in the peculiarities of personal norms (principles) concerning legally significant behavior: in the justification and admissibility of the use of illegal actions under circumstances that are subjectively assessed as compelling; in the absence of a fundamental personal intention (prohibition) not to commit illegal acts, regardless of their nature.

Legal consciousness covers the main areas of legally significant human behavior, as well as his social roles, the implementation of which is regulated by law and provides for certain obligations and prohibitions. The main spheres of legal awareness are:

1) the sphere of ensuring material interests - in relation to it, the rights, legal methods of ensuring material interests and the procedure for their implementation are determined, as well as administrative and criminal prohibitions are established, which are qualified as mercenary crimes;

2) the sphere of interaction with other people and other social subjects, including with state bodies - in this area, the rights and obligations of a capable person are established, as well as administratively and criminally punishable acts that are expressed in violent and other harmful actions against social subjects;

3) the sphere of consumption and leisure (satisfaction of needs for rest, entertainment, etc.) - for this sphere, illegal actions are defined that bring physical or moral harm to the subject himself, other people, public morality and other social values.

In these areas, a person performs various social roles, the implementation of which is also regulated by law. Thus, for persons with children, obligations are established to provide material support for minor children, to participate in their upbringing, and to take care of their health. A number of civil obligations have been established, the failure of which entails criminal liability, for example, for evading military service, evading testimony, failure to provide assistance to the victim in certain cases, etc.

In the sense of justice, one can distinguish the ideal level and the pragmatic level. In the individual legal consciousness, the ideal level is a set of value-normative ideals of the individual, which are based on opinions and attitudes concerning legally significant behavior. They determine what actions and ways of solving life problems are correct, proper, fair, respectable, as well as what are reprehensible, unfair, unworthy. These value-normative ideals are desirable for people, but not always real regulators of behavior. In terms of their regulatory function, they are

comparable, for example, with the ideal self-image, which is desirable for an individual, but not always obligatory. An individual in his actions seeks to meet ideal ideas about what he needs to be and how to act, but this desire does not always act as the dominant internal factor in motivation and decision-making to perform certain actions, since motivation and goal-setting are also influenced by other factors, such as internal and external. Based on the value-normative ideals, a person evaluates the actions of other people and his own, feels a sense of pride in him when his actions correspond to personal ideals or remorse in the opposite case.

Being in specific social conditions, he is forced to adapt to them to one degree or another and focus on the possibilities that really exist, on the social impact that is exerted on him. In accordance with this adaptation, a pragmatic level of legal awareness is formed, the basis of which is formed by subjectively permissible variants of legally significant behavior and ways of satisfying needs. They can be perceived by an individual or the majority of representatives of a social group as unworthy, but forced and justified in the given conditions due to the lack of real opportunities to satisfy needs and interests in a legal way in accordance with value-normative ideals.

As an integrative content characteristic of individual legal consciousness, it is advisable to consider its orientation, which can be represented in the continuum: lawful - illegal. The legitimate orientation of legal consciousness expresses the resulting personal predisposition to compliance with legal regulations and volitional resistance against the commission of illegal acts, including resistance to criminogenic circumstances and influences. Illegal orientation is associated with the presence of defects that act as personal prerequisites for illegal behavior. However, if the lawful orientation can characterize the legal consciousness of the individual as a whole, then the illegal one can manifest itself both in certain areas of legally significant behavior (in relation to certain law-protected values and types of illegal acts), and be relatively "global" in nature, presenting the internal possibility of committing illegal acts different kinds against different social values.

The characterization of public legal consciousness presupposes the identification of trends in the statistical distribution of various content types of the above-mentioned main components. When studying public legal consciousness, it is necessary to focus on its identification in those social groups that represent the part of the population that is most active in legally significant behavior and is significant in the formation of the level of law and order, which is characterized by the opposite phenomenon - the level of crime. Of particular importance in the study of public legal consciousness is the knowledge of its content dynamics - trends in changes in its main components. They internally determine tendencies in the legally significant behavior of members of society, i.e. tendencies of changes in the structure and level of crime, and, consequently, changes in the indicators of law and order.

Summing up, it should be noted that the presented structure of the properties of a person's legal consciousness with their meaningful characteristics serves as a theoretical and methodological basis for practical research of individual legal consciousness in order to predict the social and legal behavior of an individual. On the basis of such an assessment of legal consciousness, it is possible to purposefully carry out preventive and corrective work in relation to a person, forming the necessary content of his properties. The refraction of these provisions on individual legal consciousness on the understanding of public legal consciousness provides the basis for applied

research focused on assessing the state and trends of changes in the internal (socio-psychological) prerequisites of the rule of law and crime. Such a study can reflect the most basic characteristics of public legal consciousness, including its defects, which will make it possible to determine measures aimed at changing them.

A specific study of the legal consciousness of an individual (as well as public legal consciousness) is determined by the concretization of the sphere of social and legal behavior, in relation to which it is necessary to give a qualitative assessment of the content of legal consciousness and, on this basis, the predisposition in the behavior of the individual. Of particular importance in such a practically oriented assessment of individual legal consciousness is the formulation of generalizing conclusions. Justification of the parameters and criteria for such conclusions is one of the scientific tasks. The most important direction of applied research on the problem of the legal consciousness of the individual and public legal consciousness is also the development of diagnostic techniques.

ABSTRACT

Data gathering and production technologies have progressed quickly. As a consequence, everything becomes automated, including data storage and accumulation. Data mining is a technique for predicting previously unseen valuable information from massive amounts of data. Otherwise, we have a lot of data but little information, which may be wrong. This paper presents an overview of data mining methods, with an emphasis on the prominent decision tree algorithms (C4.5 and ID3) and associated learning tools. The accuracy has been shown using a variety of datasets.

KEYWORDS:*C4.5, Classification, Data Mining, Decision Tree, ID3.*

7. INTRODUCTION

Various companies face problems and losses on a daily basis as a result of the enormous amounts of data they collect. This is owing to a lack of enthusiasm for techniques for extracting meaningful patterns from these datasets. We need Knowledge Discoveryin Databases(KDD)to increase income and decrease losses. KDD is a method for analyzing data from different angles and gaining information[1]. Selection, transformation, interpretation/evaluation, processing, and data mining are all stages in the KDD process. Data mining is a subset of KDD, and its goal is to find useful information in massive databases[2]. As a result, data mining has piqued the attention of many academics. As indicated in Table 1, the growth of data mining is a result of the increasing usage of computerized databases to store data and give multi-level responses to businesspeople.

TABLE 1: DATA MINING EVOLUTION

Evolutionary	Question	Technology
Data Collection	What was the revenue in six months ago?	computers, tapes, disks
Data Access	What were item sales in India Jun.ago?	faster and cheaper computers with more storage, relational databases
Data Warehousing	What were item sales in India Jun.ago? Drill down to Delhi	faster and cheaper computers with more storage, On-line analytical processing multidimensional databases, data warehouses
Data Mining	What's likely to happen to Delhi item sales next month? Why?	faster and cheaper computers with more storage, advanced computer algorithms

7.1. Data Mining Techniques:

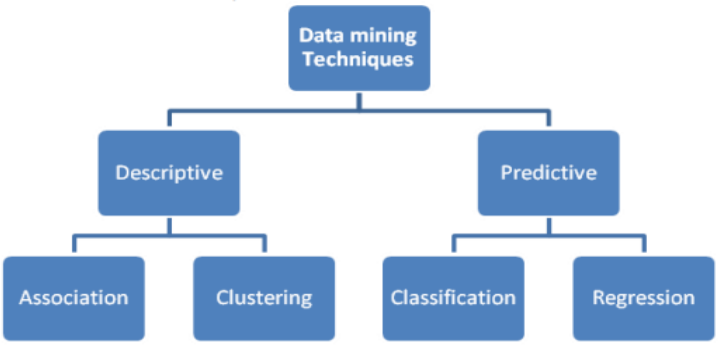

Fig. 1: Data mining techniques[3]**.**

These strategies differ depending on the needs of mining methods. There are a plethora of effective methods for data mining and retrieval. As illustrated in Fig. 1, these methods include Association, Clustering, Regression, and Classification.

7.1.1. Association:

It allows for the discovery of hidden connections between disparate variables in databases[4]. It reveals confusing patterns in the data and uses various measures of significance to pick the best rules from other rules. Lowest support and confidence levels are the best indicators.

7.1.2. Clustering:

It is the process of finding data sets that are comparable to one another in order to comprehend the differences and similarities between them[5]. It is based on distance measurements. As a partitioning method, there are two types of clustering algorithms: locality-based and grid-based.

7.1.3. Regression:

It's a method of analyzing data to determine the relationships between variables[6]. It depended on providing values to get new values. It utilizes linear regression for simple instances, while relative decline is used for complicated cases that are difficult to forecast because they rely on complex interactions of many factors.

7.1.4. Classification*:*

It refers to the categorization of data to make it easier to use and more efficient[7]. It attempts to speed up data collection and retrieval, as well as anticipate a certain impact based on available data. For example, the incoming messages to the e-mail account may be split into dates.

8. DISCUSSION

8.1. Predictive Analysis:

Predictive analysis is a kind of data analysis that involves determining unknown values for a prediction target characteristic[8]. It comprises a classification task for predicting class labels and a numerical prediction job for predicting continuous or ordered values. Learning model and prediction are two of the most important functions of prediction. The target attribute's type

determines whether the issue is binary classification or numerical prediction with continuous values. To obtain the outputs, classification refers to predicting a particular effect based on a specific input. The algorithm tries to find a relationship between the characteristics that would allow it to be reasonable to get the results. The categorization job is shown in Fig. 2.

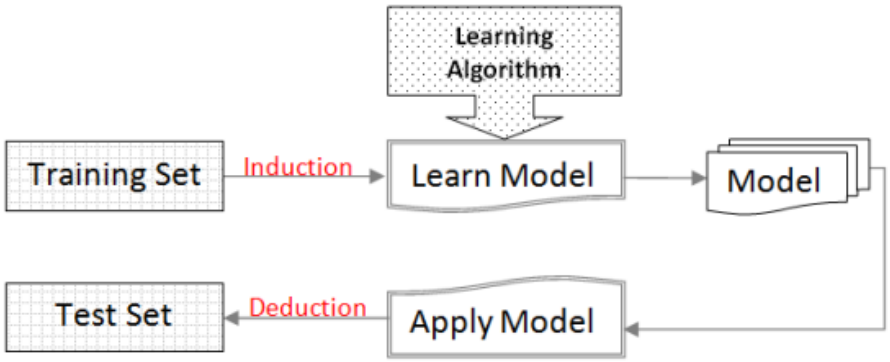

Fig. 2: Classification task steps[7].

It wraps together the functions for obtaining classes or principles for obtaining the class of objects whose class has been revealed. The examination of the training set is used to determine the steps. We utilize test data to determine the correctness of the final, optimized, and technique. The goodness of classification learning is calculated using this data set. Data mining classification techniques include decision trees, rule-based classification, back propagation, lazy learners, and others. In data mining classification, a decision tree is an essential classification method. It wraps together the functions for obtaining classes or principles for obtaining the class of objects whose class has been revealed. The examination of the training set is used to determine the steps. We utilize test data to determine the correctness of the final, optimized, and technique. The goodness of classification learning is calculated using this data set. Classification techniques used in data mining include decision trees, rule-based, back propagation, lazy learners, and others. In data mining classification, a decision tree is an essential classification method.

8.1.1. Decision Tree:

Depending on the quantity of data, the effectiveness of the method, and the amount of memory available, the Decision Tree classification technique may be performed in serial or parallel stages[9]. A serial tree is a logical model in the form of a binary tree built from training data. Using predictor variables, it aids in forecasting the value of a target variable. It is made up of sets of rules that are arranged in a hierarchical order. It's a simple recursive structure for expressing a decision process in which a future instance is categorized into current preset classes and observations are divided into mutually exclusive subgroups. Each branch of the tree represents one or more records from the original data collection. The root node (no inbound connection) is at the top of the tree and represents all of the rows in the dataset. The internal or decision nodes (with just one incoming connection) are used to test on an attribute. As illustrated in Fig. 3, the downmost nodes are called terminal nodes (no outgoing connection) and indicate a decision class.

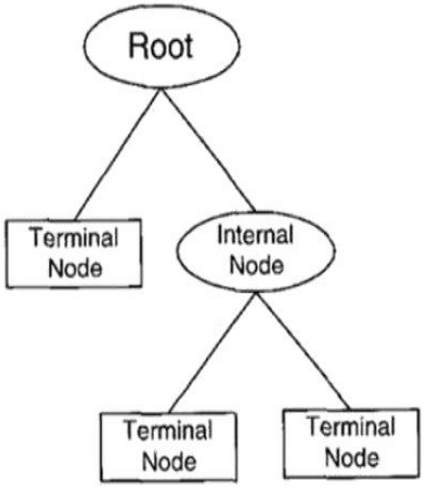

Fig. 3: The form of decision tree.

Each node produces child nodes until the subgroups are too tiny to divide meaningfully or there are no statistically significant subgroups left after further splitting. Some parts of the sample may result in a large tree, and some connections may result in outliers or erroneous results. Branches like this must be cut off. Tree pruning should be done in a way that does not have a major impact on the model's accuracy rate. We will leave the pruning to future research in our paper. Decision trees simplify the representation of data and the extraction of IF-THEN categorization rules.

8.2. ID3 Algorithm:

J. Ross Quinlan created ID3, a basic decision learning systemthat builds decision trees by testing each characteristic at each node using a top-down, greedy search over the supplied sets of training data[10]. It chooses which characteristic to test at each node in the tree based on a statistical feature called information gain. The amount of information gained by a particular characteristic determines how effectively the training examples are classified according to their goal categorization.

Let's utilize the ID3 method to see whether the timing is right for a game of baseball. The data is aggregated over the course of two weeks to aid in the construction of the ID3 decision tree shown below. The question is "Do you want to play ball?" and the answer is Yes or No.

TABLE 2: WEATHER DATA SETS

Outlook	Temp	Humidity	Windy	Play Golf
Rain	Hot	High	false	No
Rain	Hot	High	true	No
overcast	Hot	High	false	Yes
Sunny	Mild	High	false	Yes
Sunny	Cool	normal	false	Yes
Sunny	Cool	normal	true	No
overcast	Cool	normal	true	Yes
Rain	Mild	High	false	No
Rain	Cool	normal	false	Yes
Sunny	Mild	normal	false	Yes
Rain	Mild	normal	true	Yes
overcast	Mild	High	true	Yes
overcast	Hot	normal	false	Yes
Sunny	Mild	High	true	NO

We need to compute two kinds of entropy using frequency tables in order to build a decision tree:

8.2.1. Step 1: Calculate Entropy of Play Golf (Target):

Play Golf	
Yes	No
9	5

$$\text{Entropy(Play Golf)} = \text{Entropy}(5,9) = -(0.36 \log_2 0.36) - (0.64 \log_2 0.64) = 0.94$$

8.2.2. Step 2: Split Dataset into Different Attributes:

For each way, the entropy is calculated. The difference between the resultant entropy and the entropy before the split is used to compute the final entropy for the split. The Information Gain is the outcome.

		Play Golf	
		Yes	No
Outlook	Sunny	3	2
	Overcast	4	0
	Rainy	2	3
Gain=0.247			

		Play Golf	
		Yes	No
Temp.	Hot	2	2
	Mild	4	2
	Cool	3	1
Gain=0.029			

		Play Golf	
		Yes	No
Humidity	High	3	2
	Normal	4	0
Gain=0.152			

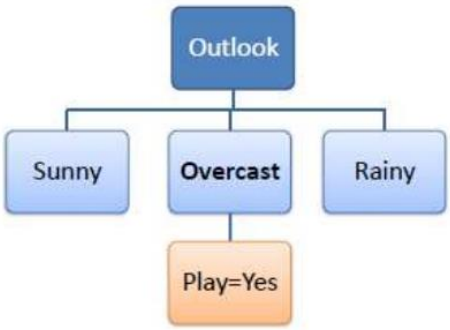
		Play Golf	
		Yes	No
Windy	False	3	2
	True	4	0
Gain=0.048			

8.2.3. Step 3: Pick Out Attribute With The Greatest Information Gain:

		Play Golf	
		Yes	No
Outlook	Sunny	3	2
	Overcast	4	0
	Rainy	2	3
Gain=0.247			

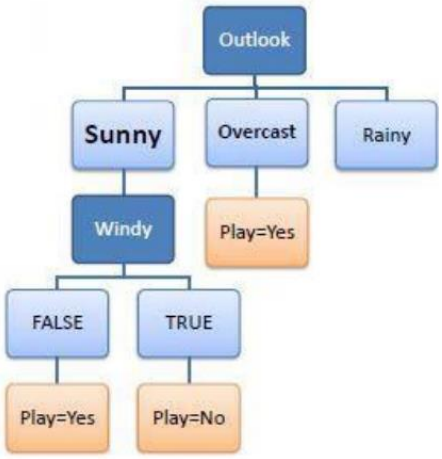
8.2.4. Step 4a: A Branch with the Entropy of Outlook= Overcast:

Temp	Humidity	Windy	Play Golf
hot	high	False	Yes
cool	normal	True	Yes
mild	high	True	Yes
hot	normal	False	Yes



8.2.5. Step 4b: A Branch with Entropy of Outlook= Sunny:

Temp	Humidity	Windy	Play Golf
mild	high	False	Yes
cool	normal	False	Yes
mild	normal	False	Yes
mild	high	True	NO
cool	normal	True	No



8.2.6. Step 5: Recursively Turned ID3 Algorithm on the Non-leaf Branches:

R1: IF (Outlook=Sunny) AND (Windy=FALSE) THEN Play=Yes
R2: IF (Outlook=Sunny) AND (Windy=TRUE) THEN Play=No
R3: IF (Outlook=Overcast) THEN Play=Yes
R4: IF (Outlook=Rainy) AND (Humidity=High) THEN Play=No
Rs: IF (Outlook=Rain) AND (Humidity=Normal) THEN Play=Yes

8.3. C4.5 Algorithm:

Ross Quinlan created the C4.5 algorithm, which is used to build a decision tree[11]. Quinlan's previous ID3 method is expanded in C4.5. C4.5 generates decision trees that may be used for classification, which is why it's frequently referred to as a statistical classifier.It was created to better handle noisy data, missing data, decision tree pre- and post-pruning, attributes with continuous values, and rule derivation.C4.5, like ID3, constructs decision trees from a set of training data, utilizing the concepts of information gain and entropy in addition to the gain ratio. The gain ratio, as we discussed previously, favors characteristics with a high number of values. If each record has a unique value for property D, then entropy (D, T) is 0 and information gain (D, T) is maximum. Quinlan proposes adopting the following ratio instead of information gain to compensate for this:

$$\text{GainRatio}(D,T) = \frac{\text{Gain}(D,T)}{\text{SplitInfo}(D,T)}$$

As a result, the gin ratio is a modification of the information gain that lowers its bias on high branch characteristics. Split Info (D, T) is information resulting from the splitting of T based on the value of the category characteristic D as follows:

$$\text{Split Info}(D,T) = -\sum_{i=1}^{K} \frac{D_i}{T} \log_2 \frac{D_i}{T}$$

8.4. Decision Tree Learning Tools And Datasets:

There is a lot of software available for data mining. We will show the experimental findings of the dataset with 10-fold cross validation using the WEKA tool. To evaluate the accuracy of ID3 and C4.5 classifiers, datasets were obtained from UCI or KEEL libraries.

WEKA is a machine learning tool that may be used to support a variety of data mining techniques. The application is written in Java and includes a graphical user interface for dealing with data files and generating visual results. The features of chosen datasets with nominal attributes and no missing values are shown in the Table 3below.

TABLE 3: DATASETS CHARACTERISTICS

Data Set	No.of Attributes	No.of Classes	No.of Instances	ID3	C4.5
car	7	4	1728	89.3519 %	94.1551 %
connect-4	43	3	67557	74.1507 %	80.1901 %
monks	7	2	124	79.0323 %	80.6452 %
nursery	9	5	11025	97.9955 %	98.6032 %
promoter	58	2	106	76.4151 %	81.1321 %
tic-tac-toe	10	2	958	83.2985 %	86.4301 %
voting	17	2	435	94.2529 %	94.4828 %
zoo	17	7	101	92.0198 %	98.0792 %
kr-vs-kp	37	2	3196	99.4871 %	99.6055 %

The accuracy of each dataset while using the ID3 and C4.5 methods is shown in Fig. 4.

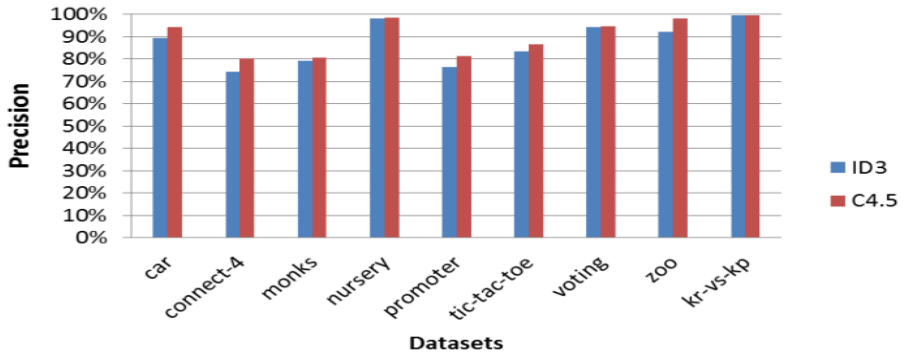


Fig. 4: The precision of ID3 & C4.5.

Other characteristics of datasets with both continuous and discrete variables with missing values may be handled. By utilizing unsupervised discretization to transform continuous characteristics into categorical attributes and pre-processing to replace the empty cells, the ID3 algorithm is unable to handle these features.

9. CONCLUSION

Data mining is a set of algorithms used by offices, governments, and businesses to forecast and create patterns with particular goals in mind. We have provided an overview of data mining development, methods, and predictive analysis in this paper, with an emphasis on C4.5 and ID3 decision trees, as well as a comparison between them when applied to various types of data with varying values. Finally, the C4.5 method is similar to the ID3 algorithm in that it uses uncertain or missing data, accepts various weights for attributes, and builds the tree before pruning it (pessimistic prediction).

ABSTRACT

In this article, we look at how traditional plants are utilized throughout the globe to cure infectious illnesses caused by bacteria. Antibiotics were discovered in the early twentieth century and provided a tool against microbial infections, and even though due to multiple drug resistance and adverse effects on the host, such as hypersensitivity, immune suppression, and allergic reactions, there is a need for natural medicines with a safer and more effective therapeutic effect. Secondary metabolites found in medicinal plants of natural origin, such as alkaloids, steroids, tannins, and phenolic compounds, may exhibit antibacterial action via a variety of methods. These active constituents exert their therapeutic action by destroying the microbe's cell membrane, membrane proteins, and enzymes situated on the cell membrane, among other things. Root extract of herbal medicines with low inhibitory concentrations against microbial illnesses address the demand for a safe and effective anti-infectious drug.

KEYWORDS:*Antimicrobial Activity, Minimum Inhibitory Concentration, Secondary Metabolites, Extract.*

INTRODUCTION

More than 80percent of the surveyed of the world's population, according with World Health Organization (WHO), rely on traditional medicine for their basic healthcare requirements. Plants have long been used as a source of medicine, and they have played an essential part in health services all throughout the world. Herbal medicine has relatively long history interactions with the environment all throughout the globe. Traditional medicine plants include a variety of chemicals that may be utilized to treat both chronic and infectious illnesses. Diseases may be

caused by microorganisms. Viral, bacterial, and fungal infections are all extremely common in the human body[1]. Antibacterial were discovered in the early twentieth century and became an increasingly significant weapon in the fight against bacterial infections. However, multiple drug resistance has evolved as a result of the indiscriminate use of commercial antimicrobial medicines widely employed in the treatment of infectious illnesses.

In addition to this issue, antibiotics have been linked to host side effects such as hypersensitivity, immunological suppression, and allergic responses[2]. This necessitates the development of novel antimicrobial treatment drugs that are both effective and safe. In this respect, naturally occurring medicinal plants with active components that have antibacterial action may offer a large study field. Plant-derived antimicrobials have tremendous therapeutic promise. They are efficient in the treatment of infectious illnesses while also avoiding many of the adverse effects that synthetic antimicrobials are known for. Plant materials' positive therapeutic effects are usually due to a mix of secondary compounds found in the plant. Secondary metabolites in plants, such as alkaloids, steroids, tannins, and phenol compounds, flavonoids, steroids, resins, fatty acids gums, and flavonoids, steroids, resins, fatty acids gums, are capable of generating specific physiological effect on the organism[3].

Active Components of Medicinal Plants Have Different Mechanisms Of Action

Various bioactive controlling the operation includes cytoplasmic membrane disintegration, proton motive force instability, electron movement, active transport, and cell content coagulation. Natural oils feature hydrophobic components that enable lipids from the bacterial cell membrane to participate in antimicrobial activity, disrupting cell structures and making them more permeable. Essential oils include chemical components that interact with cytoplasmic membrane proteins. ATPase enzymes are known to be found in bacteria's cytoplasmic membrane, surrounded by lipid molecules. Cyclic hydrocarbons bind to these enzymes and act on them. Furthermore, lipid hydrocarbons may alter the lipid-protein interaction, and lipophilic substances may bind directly with hydrophobic regions of the protein. Some essential oils promote pseudo-mycelia development, indicating that they may effect on enzymes engaged in the making of bacterial structural components[4].

Plant Dyes as Antimicrobial

Despite the many advantages of natural dyes and antimicrobials, there are certain disadvantages that limit their use. Some key advantages and limitations of natural dyes/antimicrobials applications are described in the following paragraphs[5].Plant products make up the largest portion of all natural antibacterial agents. Some plant products have been utilized for healing purposes since ancient times. Plants can produce a nearly infinite number of aromatic compounds, the majority of which are phenols or their oxygen-substituted derivatives. The majority of them are secondary metabolites, with at least 12,000 having been identified. These substances are often used by plants to protect themselves against microbes, insects, and herbivores. Plant smells are caused by certain chemicals, such as terpenoids, whereas plant pigments are caused by others. Plant flavor is caused by a variety of chemicals[6].

Extraction Techniques

The most essential stage in achieving the required dyeing characteristics and/or antimicrobial activity on textiles is to extract dyes/antimicrobials from natural sources. Obtaining a standard extraction method and optimizing the relevant factors for a certain natural source are also economically significant and have an impact on product prices[7]. The next paragraphs will describe the various ways of extracting these minerals from natural resources:

• Aqueous Extraction

The chemical nature of the majority of natural dyes/antimicrobials enables for the use of the most commonly utilized and simple-to-set-up aqueous extraction method. Typically, dried and finely cut natural resource material is crushed into powder, and the dye/antimicrobial is extracted in water using several conventional methods. To make a crude extract, the aqueous solution may be filtered and concentrated under decreased pressure (rotary evaporator). The choice of solvent is critical in the natural dye extraction procedure. Different solvents were used in order to improve the natural dye extraction yield from Gardenia jasminoides Ellis, which included crocin as the primary colorant, in a recent study. Fifteen different solvents were tested, and those that produced colors that were similar to the goal color were combined with water in various ratios to determine the condition that would produce the color that was closest to the target color. To produce dyes with high absorbance and as near to the desired color as feasible, four solvents (methanol, ethanol, 1-propanol, 2-propanol) with Hansen solubility characteristics comparable to crocin and low chi parameter values were selected. The four solvents were then combined in different volume ratios with distilled water[8].

• Extraction Using an Alcoholic or Organic Solvent

Some organic dyes/antimicrobials are extracted from natural resources using non-aqueous extraction techniques. Natural colors are extracted using a combination of organic solvents, typically alcohols and hexane, in this technique. The roots of the genuine Ratanjot sample, for example, were air-dried and crushed to a coarse powder. The powdered roots were extracted in a soxhlet device with n-hexane until the decoction's color became extremely light. The solvent was extracted from the roots, and the yield percentage of the hexane extraction was determined.

• Extraction Using Ultrasonic Waves

The frequency of ultrasonic waves increases the extraction yield in this technique. During a known mechanism known as "cavitations in liquid media," which includes the growth and explosive collapse of microscopic bubbles producing localized high temperature and pressure, shock wave, and shear force breaking chemical bonds, ultrasound improves the efficiency of various chemical and physical processes. Several efforts have been made to investigate and utilize this technique for colorant extraction and application. The main influential factors on the process efficiency are the extraction bath pH, salt concentration, ultrasonic power, extraction time, and temperature. Enzyme aided extraction is a cutting-edge extraction technique that is extensively utilized nowadays owing to its great efficiency when compared to traditional approaches. The enzyme-treated material was rinsed with distilled water before the pH of the solution was adjusted. At the appropriate temperature, the sample was shaken at 150 rpm for 20-80 minutes. To eliminate solid contaminants, the contents of beakers were filtered through a conventional test sieve, and the concentrated dye extract was vacuum evaporated in a rotary vacuum evaporator to approximately half of its original volume, before being spray-dried.

• Extraction Aided By Microwave

Microwave heating (volumetric heating) is much faster than traditional surface heating. Microwave aided extraction is claimed to reduce extraction time and energy input to a large extent. Various academics have lately focused their attention on using microwave radiation as a contemporary technique for extracting natural minerals. This is due to the process's cleaner nature, reduced energy usage, and greater yield when compared to traditional extraction techniques. Dabiri et al. improved the microwave aided extraction (MAE) technique of two common dyes from Rubiaceae plants, alizarin and purpurin, and compared its effectiveness to ultrasonic and reflux extraction methods. The greater quantity of crude material recovered (varying from 84 to 94 percent), shorter extraction time (20 min vs. 6 h), and lower solvent

consumption all contributed to MAE's superiority (20 vs. 100 ml). Natural color extraction from pomegranate peel and Annatto is another example of the MAE method. Influencing factors such as extraction time, solution pH, and crude material weight have been simulated, optimized, and compared to those used in traditional methods. Improved dye yield and a significant reduction in extraction time were used to show MAE's superiority over the traditional aqueous extraction technique. It was also shown that under microwave irradiation, the dye ability of acrylic fibres may be substantially enhanced as a consequence of increased dye adsorption into fibres owing to local overheating and amplified reaction likelihood between the dye and fibres.

Processing Of Fabric with Different Extracts

a) Aloe Vera(ALOE BARBADENSIS MILL)

The Aloe Vera plant, which belongs to the Liloaceae family, is known as the "desert lily." For almost 2000 years, Aloe Vera is being used as a skin product. Scientific study has also shown that Aloe leaf contains approximately 75 nutrients and 200 active chemicals, including 20 minerals, 18 AA, and 12 vitamins, according to current research.Aloe Vera contains a variety of polysaccharides, including glucomannan of various molecular weights, acetylated glucomannan, gaalactogalacturan, glucogalactogannan of various compositions, and acetylated mannan or acemannan. Pad-dry-cure method was used to impart antimicrobial finishing on cotton woven fabric using Aloe Vera extract at different concentrations in the presence of eco-friendly cross-linking agent glyoxalin.

b) **Papaya Seed**

The papaya seed and leaves were gathered and properly cleaned. It was dried for 15 days and ground to powder using a mixer. 5 grams of powder were combined in 100 milliliters of distilled water, while 70 percent methanol was used for the solvent extract. At 4 degrees Celsius, the solvent extract was maintained in a water bath for one hour. The filtrate was collected after the extract was filtered using filter paper to decrease the volume to 10%. The lack of an OH group at ortho position, which is responsible for binding the extract to the fabric, prevented it from being applied to the substrate.

c) **Neem (AZADIRACHTAINDICA)**

In Ayurveda, Unani, and homeopathic medicine, neem is extensively utilized. For its many uses, neem has been found to have over 140 bioactive components. Mahesh et al used neem extract on cotton fabric to conduct a comparison study of the dip-dry and exhaust methods. According to reports, the exhaust technique is superior to the dip-dry method. Joshi investigated the effectiveness of neem seed and bark extracts against Bacillus subtilis on cotton and cotton/polyester mix fabrics. The impact of neem extract on diapers was compared to that of several synthetic antibacterial agents by, who found that natural agents' activity was comparable to that of synthetic agents. The Neem powder was used to make a methanolic extract, which was kept for 48 hours. The methanol was then evaporated using a rotary evaporated method. Using the dip padding method, the extract was applied to the cloth.

d) **Banana (Leaf and Peel)**

100g banana peels were chopped into tiny pieces and cooked in 1L of 0.1 percent NaOH solution. The extract was obtained after filtering the solution using filter paper. The dyeing bath was heated to 800°C for 90 minutes while continuously swirling the banana peel extraction. The textiles were washed with water after dying and air-dried.

e) **Mango**

The leaves were gathered and carefully cleaned in water. It was dried in the sunshine before being crushed into a fine powder using a grinding machine. The extraction was place at 980C for

60 minutes using the aqueous extraction technique. To get a clear solution, the extract was filtered three times using filter paper. In the water bath, dyeing was done at 800C for 60 minutes at MLR 1:50. The coloured cloth was dried for two minutes at 800°C.

f) **Pomegranate (PUNICAGRANATUM)**

Vitamins A, D, B, and calcium are abundant in pomegranates. It contains 1.2 g of total fat and is extensively utilized in Ayurvedic treatment. Gupta29 investigated the antimicrobial properties of pomegranates and their impact on cloth. The fabric's stiffness and tensile strength increased, as did its longevity, which may be enhanced further by micro encapsulation or the use of a cross linking agent. The antibacterial activity of pomegranate on cotton fabric was tested using the dip technique and then the exhaust method, with the exhaust approach being effective against both Gram positive and negative bacteria, but more effective against Gram negative bacteria 24. Sathianarayanan22 utilized three techniques (direct, micro encapsulation, and cross linking), and wash durability showed found to be better on the cloth coated with micro encapsulation and a silane coupling agent.

Early Application of Natural Dyes/Antimicrobials On Textiles

Colorants are derived from many sections of plants, including the bark, leaf, root, seed, and flower, and include common colour structures like tannin, flavonoids, quinonoids, and others. The examples of early uses of these extracts are categorized in the following sections according to the various portions of plants utilized as natural resources.

A.Root Dyes and Antimicrobials

The root is one of the most frequent components of the plant that has been used to extract colours and antimicrobials. Gupta, et al., investigated the dyeing of nylon using an extract of madder, the ground root of the Rubia species with an anthraquinone substituted chemical structure, as an example of application. Purpurin was isolated from madder and used to color nylon fibers. It has a structure of 1, 2, 4- trihydroxyanthraquinone. The isolated red pigment has a high affinity for nylon fibers, according to the scientists. In a similar study, the light fastness of madder extracts applied on nylon was also investigated[9]. Purpurin and munjistin, two pigments derived from Indian madder by soaking and extracting with alum, were used to dye nylon using ferrous sulfate, copper sulphate, alum, and stannous chloride as mordants. The textiles had excellent light fastness, but the dye fastness of the fabrics colored with munjistin was poor, according to the authors. Montazer and Parvinzadeh also colored wool yarns using madder and aluminum potassium sulfate as a mordant, and then treated them with various ammonia solutions. During wash fastness testing, the dyed samples changed color, while light fastness tests revealed that the madder-dyed yarns faded more following ammonia treatment. Ammonia's impact on the coloristic characteristics of wool dyed with madder and other natural dyes containing anthraquinone, naphthaquinone, flavone, and tannin structures was also studied. Madder, cochineal, walnut husks, weld, red and white onion skins, and pomegranate shells were used to dye aluminum-mordanted wool, with the color variations attributed to the expansion of the dye molecule conjugated system by one lone pair electron in ammonia solution.

B. Seed Dyes and Antimicrobials

Plant seed may be a significant source of natural colors and antimicrobuals. Bixin, a natural dye found in annatto seed containing carboxylate groups, may be called a natural acid dye. The amino groups in protein fibers are protonated when pH decreases, and the ionic interaction of bixin carboxylate anions with amino cations increases, resulting in increased affinity and dye absorption. The color imparting ability of mordants for both wool and silk fibers was found to be in descending order with bixin dye: ferrous sulfate>aluminumsulfate> magnesium sulfate> no salt, which was attributed to the ease and speed with which iron and aluminum formed salts with

bixin when compared to magnesium. Using bioactive compounds derived from ban-ajwain seeds, Thymus serpyllum, I attempted to impart a bactericidal finish to cotton textiles[10]. Direct application, microencapsulation with acacia gum, cross-linking with resin, and a combination of these methods were used to include the extract. In direct application, the finish's resistance to washing was extremely poor[11].

C. Leaf Dyes and Antimicrobials

Color was obtained from the leaves of several plants in certain experiments. Eucalyptus camaldulensis, for example, is a significant source of natural polyphenols and tannins. Leaves having 11 percent quercetin as the main component, as well as other components such as rutin, gallic acid, ellagic acid, and other minor components, are extremely helpful in coloring yield and substrate durability. Wool fibers had a greater color strength than silk fibers, and both wool and silk were able to produce a broad range of colors, including yellowish brown with aluminum and copper, dark grayish brown with iron, and brilliant yellow with tin. Both substrates had UV protection, and textiles had excellent to very good wash fastness, as well as medium to good light and rub fastness. The tea plant, Camellia sinensis, is a rich source of antioxidants, flavanols, flavonoids, polyphenols, and catechins, among other helpful natural components. It is processed in a number of ways to create green, yellow, dark, white, oolong, and black teas. Deo and Desai looked into dyeing cellulosic textiles, cotton, and jute using an aqueous extract of black tea, where the tannins were the primary coloring agents. The black tea solution was mixed, heated, and allowed to boil for 30 minutes before being filtered and used as a black pigment for dyeing textiles using ferrous sulfateheptahydrate, alum, and copper sulfatepentahydratemordants. Jute textiles with a deep color tone and good to outstanding wash and light fastness were created[11].

D. Fruit Dyes and Antimicrobials

Plant fruits are another source of natural dyes, and their use in textile coloring has been widely researched. Pomegranate rind extract, for example, was utilized for a bi-functional treatment of cotton, which included both coloring and a bactericidal finish. Punicagranatum is a deciduous shrub or small tree that bears the pomegranate fruit. The dye was extracted using a water/ethanol solvent and was shown to have a high affinity for cotton. Wash, light, rub, and sweat fastnesses were achieved, as well as good antibacterial properties against common bacteria such as S. Aureus and E. coli. However, as washing cycles progressed, the antibacterial activity gradually deteriorated. Pomegranate peel has also been used to color wool and silk, either with or without mordants. The optimum dyeing pH was discovered to be 4, which resulted in grey and yellow colors on fibers, respectively, from iron and aluminum. Mordanting enhanced dye absorption and light fastness but had no effect on wash fastness.

DISUSSION

The emergence and spread of multi-drug resistance bacteria is a significant worldwide health care issue that poses a danger to human life. We must recognize that the fight against these germs is never-ending, but we may win by shifting our approach and returning to nature, utilizing active compounds derived from plants that have endured millions of years in the face of microbes. Following the demise of antibiotics, a large number of research on the antibacterial properties of selected medicinal plants against MDR and non-MDR microbes have been performed. However, only a small percentage of these attract pharmaceutical firms. Extracting medicines from therapeutic plants, especially those described in traditional and folk medicine, should be of serious attention. Hopefully, antimicrobial research based on medicinal plants will provide positive results.

CONCLUSION

We concluded from the research that the antibacterial activity of extracts of medicinal plants is dependent on a number of factors, including the plant material utilized, the method used, the growing medium used, and, most significantly, the microorganism examined. Plant material of higher grade should be used for better study. Both the solvent and the extraction method have the potential to change the ultimate outcome. The effects of various extracts of a medicinal plant may vary. In vitro studies of garlic revealed that the activity of garlic powder against most bacteria was higher than that of the plant or crude medicine; nevertheless, garlic oil has even more therapeutic potential. It was shown that the diethyl extract obtained after extraction of the aqueous suspension of the drug powder had moderate activity against Escherichia coli, but that no active extracts or fractions were found when a sequential extraction with petroleum ether, dichloromethane, dichloromethane–methanol, and methanol was used.

ABSTRACT

In the field of healthcare, big data has opened up a new door. Because of the many advantages and possibilities, it has piqued the interest of all stakeholders in the healthcare sector. This chapter seeks to provide you a broad yet in-depth knowledge of big data in healthcare. The healthcare of big data, as well as various healthcare data analytics, such as predictive and prescriptive analytics, is covered in this chapter. The obvious benefits of adopting big data technology in healthcare are discussed in detail. The application fields are also addressed, as well as a variety of actual use examples. Managing large amounts of data is always a difficult task. The chapter outlines all of the potential roadblocks to achieving the advantages of big data in healthcare. A short overview of the tools and platforms, architectures, and commercial infrastructures for healthcare big data is also provided in this chapter.Healthcare professionals are now persuaded of the advantages of Big Data and are convincing themselves to analyze the data in order to extract new insights that have provided them with promising new strands of knowledge that are being converted into creative and meaningful activities.

KEYWORDS:*Big Data, Healthcare, Medical, Public, Reduction.*

1. INTRODUCTION

The healthcare sector is undergoing a radical transformation. A huge quantity of data is being generated as a result of major advancements in digital, open, and ubiquitous healthcare systems. Because this healthcare data is similar to Big Data in both scale and type, it is referred to as healthcare Big Data[1]. Though the healthcare sector has lagged behind in the use of Big Data technology when compared to other industries, the changing medical and clinical environment has pushed stakeholders to dive into the development rapidly. Big Data has unexpectedly become critical for almost every operational, clinical, and managerial activity. Several applications in healthcare are well-suited to Big Data technology[2].

Healthcare Big Data analytics has opened up numerous interesting possibilities in various healthcare operations, such as diagnostic and medical treatment, clinical decision support, population health management, and so on. The success of healthcare Big Data is largely reliant on the effective gathering and storage of vast amounts of heterogeneous data obtained from a variety of sources, as well as the analysis of that data. The proper use of healthcare Big Data and information gained via analytical procedures has the potential to save a considerable amount of money and, more significantly lives[3]. Our period has been dubbed the "electronic age," and the amount of data produced is increasing at an exponential pace. As a result, an increasing number of businesses are grappling with the challenge of handling enormous quantities of data. Many sources, including corporate operations, transactions, and social networking sites, create a data Btsunami that persists in both organized and unstructured forms.

There are many legal methods and purposes for collecting and analyzing these data sets, including invoicing, inventory, forecasting future requirements, and many more[4]. This data avalanche is often referred to as Big Data, and it is one of the most challenging problems that businesses confront today. According to Richards and King, our community is one step away from a Big Data Revolution, similar to the Industrial Revolution, since it has the potential to impact all aspects of human life (e.g., health, education, voting, law enforcement, and cyber-security). The processing and analysis of massive amounts of data is a difficult job. To manage and analyze Big Data, a variety of techniques and technologies have been created[5]. These methods are based on mathematics, statistics, computer science, and economics, among other disciplines. These processes imply that, in order to extract value from Big Data, an organization must adopt a more flexible strategy that is interdisciplinary in nature. Experts from a variety of disciplines and backgrounds are interested in gaining access to large amounts of data and debating the possible advantages and costs of studying it. The current tendency is to shift from in vivo to in silico, since novel research may arise from the study of existing data sets[6]. The impact of Big Data is so great that these data mountains and analyses are changing the way science progresses. Furthermore, there is a critical need to combine or even replace laboratory experimental data with data from in-field use, which provides insight into real-world stressors.

Big Data's significance and potential are enormous, and many academics have already worked on related problems. This article focuses on a distinct set of issues, those concerning ethics and difficulties that arise as a result of the usage of Big Data in the Healthcare era[7]. In general, experts anticipate that the digital revolution will improve healthcare quality, reduce costs, and offer doctors and researchers with new tools and resources derived from vast healthcare data sets and resources. This article summarizes some of the most important debates about the difficulties and ethics of big data in healthcare. The focus of the article is on the effect of Big Data on society, but its impact on individuals is also shown. The emphasis is mostly on the impact on society, the general public (customers, citizens, and patients), and Big Data users (both those who created the data and those who utilize it for study).

The purpose of this article is not to provide a thorough overview of Big Data technologies, but rather to increase awareness of the issues that healthcare professionals must deal with. We want to provide you a broad overview of Big Data in Healthcare as a discipline. First and foremost, we will examine the difficult concept of Big Data. Second, we explain the Big Data issue in general. The framework for Big Data in Healthcare is given in the third section. Finally, we developed a three-dimensional model for evaluating Big Data issues in the medical field. This approach is intended to identify and analyze the difficulties and ethical concerns that Big Data in Healthcare brings up. Finally, recommendations for further research and conclusions are made. Big Data is characterized by enormous data quantities (terabytes and beyond) and a variety of data kinds (structured, unstructured, semi-structured, and poly-structured data) derived from diverse data sources that are frequently geographically dispersed. The proliferation of fresh data is so large

that analysts estimate that 2.5 times 1018 bytes are created each day. Rather than Terabytes, we're talking about Petabytes, Exabyte's, Zettabytes, and even Yottabytes. Big Data, which is expected to rise to 5247 gigabytes for each of the world's human population by 2020, and Big Data Mining are already commonplace.Despite the fact that Big Data is a recently created and frequently usedphrase, Boyd and Crawford argue that it is a bad term in many respects.

As the quantity and diversity of data grows, describing Big Data as a catchall phrase may be difficult. Big Data is often defined in technical terms as "data that exceeds the processing capability of traditional database systems". The phrase Big Data refers to enormous amounts of data that are larger than the capacity of most widely used software tools to collect, manage, and analyze the data in a reasonable amount of time. Big Data volumes are presently ranging from a few terabytes to several petabytes of data per data set Manovich observed that the phrase "big data" has been used to "data collections large enough to need supercomputers"[5]. The ability to explore, combine, and cross-reference huge data collections is referred to as Big Data. Big Data is defined as "large volumes of high velocity, complex, and variable data that require advanced techniques and technologies to enable the capture, storage, distribution, management, and analysis of the information," according to a report presented to the United States Congress in August 2012[8].

1.1 Advantages Of Big Data In Healthcare:

Healthcare Big Data is created by digitizing data from patient records, medications, medical imaging, laboratory, pharmacy, and insurance. This massive quantity of data has the potential to provide knowledge trails that would enhance the quality of medical and healthcare services considerably[9]. The Big Data analysis would provide useful insights that would aid in making informed choices, illness monitoring, and other medical and healthcare services. The inferred information will be beneficial to patients, doctors, healthcare organizations, pharmaceutical firms, legislators, and other stakeholders. Individual and people in mass health surveillance; predicting individual health issues such as calculating the medical complication and risk associated with a patient, disease progression or progression; analysis of the particular kind of treatment suitable for the person; analysis of current treatment strategies to detect whether the diagnosis and applied treatment are correct; analysis of current treatment strategies to detect whether the diagnosis and applied treatment are correct; analysis of current treatment strategies to detect whether the diagnosis and applied treatment are correct; analysis of current treatment strategies to detect whether the diagnosis and applied treatment are correct; It may provide information about the patient's present and future health, allowing them to make more educated decisions. The incorporation of Big Data applications into existing medical and health services is beneficial in terms of scaling health care quality and accountability some of the benefits are described below[10].

- **Health-Care Cost-Reduction***:* The current healthcare system is built on a disease-centered paradigm, in which doctors recommend therapy based on illness symptoms and test results. Treatment is based on clinical knowledge and medical data, and additional treatment choices are recommended depending on treatment outcomes. Recursive, time-consuming, and expensive treatment methods are used. With the massive quantity of data on medical situations, treatment patterns, medications and their efficacy, and genetic data, healthcare Big Data provides for a patient-centered therapy approach. This information enables for accurate patient analysis and diagnosis, as well as the prediction of the proper therapy plan. Big Data in genomics, for example, allows for customized profile and, as a result, tailored medication for patients, allowing for precise treatment. Big Data inferred knowledge in healthcare really reconciles the redundant and expensive treatment process.

- **Reducing Hospital Readmissions:** Patients are more likely to return to the hospital within a month after receiving therapy. The hospital will have to pay for this in terms of both money and resources. Patients at risk of medical problems and readmission may be identified using Big Data analytics applied to their medical records, histories, chart information, and lifestyle records. As a result, identifying patients who need extra care may help decrease hospital readmissions.
- **A Workforce That Is Optimized:** Hospitals and other health-care institutions are grappling with the age-old issue of staffing and scheduling. There is a danger of underutilization of resources if a large number of people are hired, yet reducing the number of people may result in bad customer service. The use of Big Data may help solve this issue. Big Data can accurately estimate the number of patients who will arrive on a daily and hourly basis using data gathered from different sources. In addition, analyzing hospital admission records over a period of years may provide insight about the kind and quantity of patients who will be admitted to the hospital in the future. When data science is used to crunch raw data, it produces knowledge that allows the company to optimize its personnel based on future needs.
- **Notifications in Real Time:** Real-time alerting is one of the most valuable features of Big Data. When Big Data is integrated into hospital and clinic services, it may analyze patient medical data in real time and give recommendations to doctors for prescriptive decisions. Further, data gathered by wearable devices is analyzed in the cloud in conjunction with Big Data to provide real-time information about a patient's present medical problems, future medical illness, and preventative actions. The physicians would be able to examine the health condition of individuals in society and, as a result, take remedial action if any deviations were noticed based on the data gathered over time. The health organization also uses real-time data to respond quickly to any alarming patient monitoring findings.
- **Examining EHRs:** A clinician may get a better understanding of treatment patterns, effects, and adverse effects by analyzing the massive electronic health record. Furthermore, Big Data enables physicians to share updated patient data for treatment, as well as medical situations, eliminating duplication tests and treatment procedures.
- Analyzing Hospital Networks: Analyzing hospital care and management data could be useful in administering critical medical condition cases, developing strategies for reducing postoperative infection, and examining the medicine (antibiotics) and treatment procedures used by doctors that were found to be ineffective in curing patients.
- **Public Health Control Data:** Medical and health organizations, hospitals, and small clinics generate massive amounts of medical information. For medical experts, there is a lot of data. Because the majority of the data is unstructured, cluttered, and raw, medical professionals and policymakers may find it challenging to utilize these data in their raw form in public health legislation and decision-making. There's a disconnect between what doctors desire and what data is available. These data are useless until they are combined with Big Data. Data analytics may be used to standardize and regularize public health data, filling in gaps and giving information that can be used in different regulatory and research efforts to improve care and health services.
- **Medical Procedures That Are More Efficient:** Big Data assists in the delivery of excellent patient care. Big Data analytics provides physicians with information on illnesses, their symptoms, treatment patterns, and drug efficacy at various phases of sickness, allowing them to treat patients more effectively.

- **Informed Strategic Planning Based on Health Data:** Big Data on public health data like vaccinations, distribution, and availability of medical services allows for the development of public health plans in the event of disease outbreaks or an increase in the incidence of chronic illness among the population. Big Data may be used to map needed services throughout an area in contrast to existing services, allowing for inferences about what actions are required to address public health problems.
- **Health-care workflows:** Multiple departments, limited patient admitting capacity, limited physicians and personnel with variable schedules, and a varying flow of arriving patients with various needs and treatments make hospital healthcare services highly dynamic. The patient's health problems are complicated by the fact that they need care from several departments and doctors at various phases of therapy, as well as laboratory testing and medicines. In addition, there have been instances of medical complications as a result of incorrect diagnosis and treatment, as well as hospital readmissions. This high-risk environment necessitates a meticulously designed and controlled process that is ready for an emergency and changing circumstance. Healthcare data enriched by multiple sources of data such as real-time patient data (patient health status, location, etc), medical records of patients, nursing information, laboratory data, and machine status (available, working, etc.) assists in identifying the current operational state of the hospital and thus allows for informed decision making for better healthcare services by maximizing resource utilization.
- **Improved Safety Methodologies:** Postoperative infections are often suspected in individuals who have had surgery. Big Data analytics of electronic medical records may provide valuable insights about a patient's vulnerability to infection in the past. Preventative measures such as rigorous surgical care, pre- and postoperative preventive medicine, and so on are ensured.
- **Patient Participation:**Patient engagement, which leads to patient awareness, retention, and proactive treatment, is one of today's healthcare problems. The healthcare sector receives a lot of funding, yet patients are never adequately cared for, resulting in more serious health issues. Insights, communication, personal wellness monitoring, medical management, new illness diagnosis, personal history, vaccination, health cost planning, social services research, and clinical trial involvement are all examples of patient engagement. Patients want to be involved because they want to be informed, involved, and confident. This increases the pleasure and experience of patients, resulting in a better outcome. Interactions with doctors, hospital and clinic staff, pharmacies and pharmaceutical companies, laboratories, and other counseling personnel improve patient involvement. Controlled and up-to-date information on the patient enables the service provider to tailor services to the patient's needs, allowing people to become more involved in the management of their health problems. Big Data has played a larger role in recognizing the issue.Healthcare professionals may use Big Data knowledge to identify people who have a serious illness or who need assistance with insurance, medical counseling, treatment, and management of their medical situations. These individuals are kept up to date on a regular basis. Patients are either texted or phoned with a customized message. People become more conscious of their own particular path as patients as a result of the customized messaging. When a patient contacts a clinic or hospital for healthcare, the physician or hospital staff may already be aware of the patient's history, communication preferences, and healthcare journey thanks to Big Data technology.
- **Big Data Is Aiding in the Prevention of Unnecessary Emergency Room Visits:**Patients often visit numerous hospitals and clinics for the same or different illness or disease, resulting in repeated treatment procedures, treatment discontinuity, and, in the worst-case scenario, incorrect therapy, putting their health in danger and wasting money and time. In

this regard, the use of Big Data would assist patients in minimizing needless trips to medical and health authorities, as well as ensuring that treatment is on track. When a patient transfers between hospitals/ clinics or receives a new treatment for an illness, the staff will be aware of the patient's medical history, treatment procedures performed, drugs given, and the results of different lab tests that have previously been performed thanks to Big Data. This significantly simplifies patient diagnosis, lowering patient workload and improving patient satisfaction.

2. DISCUSSION

Life science and healthcare are flooded with information and data sets in the era of Big Data. There are many views on instability and difficulties in the region, but changes are taking place in many areas to address them. As Mateo Sian points out, the field of Big Data is barreling down on us like a freight train. As a result, the growing problems of Big Data cannot be overlooked, and they must be thoroughly investigated and appropriate measures taken in many areas. The achievement in overcoming the interoperability of the necessary Big Data management systems is an important step in this approach.Additionally; steps should be made to improve data gathering and storage. Experts in healthcare information technology should create software that can manage data from EHRs. Experts should also assess error rates and describe the degree of data accuracy uncertainty. The bottlenecks in healthcare Big Data are many, and they are not limited to the problems described in the sections above. Accuracy problems (healthcare datasets are full of biases), consistency (standards need to be established), and facility (tools should be developed to allow patients to correctly self-report data) are some of the obstacles that are especially linked to healthcare Big Data. To reap the benefits of Big Data, healthcare companies must commit time and money to its management. Healthcare companies should also create an intelligence center with a focus on Big Data and mobile computing, and develop a plan based on their goals and technical maturity. They should also work with partners that can assist them with hosting and programming platforms, security concerns, internally and externally integration, and app development.

3. CONCLUSION

In recent years, Big Data has had an impact on virtually every industry. The healthcare industry is no exception. The healthcare sector, in reality, is the leading generator of digital data. In the field of healthcare, big data technologies have opened up new possibilities. It has benefited not only the patients, but also the healthcare facilities and hospitals. Adoption of the appropriate Big Data technologies and the underlying architecture should be carefully considered to maximize the advantages. Despite the fact that Big Data technology has had a major effect on contemporary healthcare, it still has to advance in order to reach its full potential. The conventional healthcare system is still struggling to adjust to the "major" shift. Nonetheless, Big Data has put the healthcare sector on the correct track toward fast change, that will undoubtedly benefit humanity.

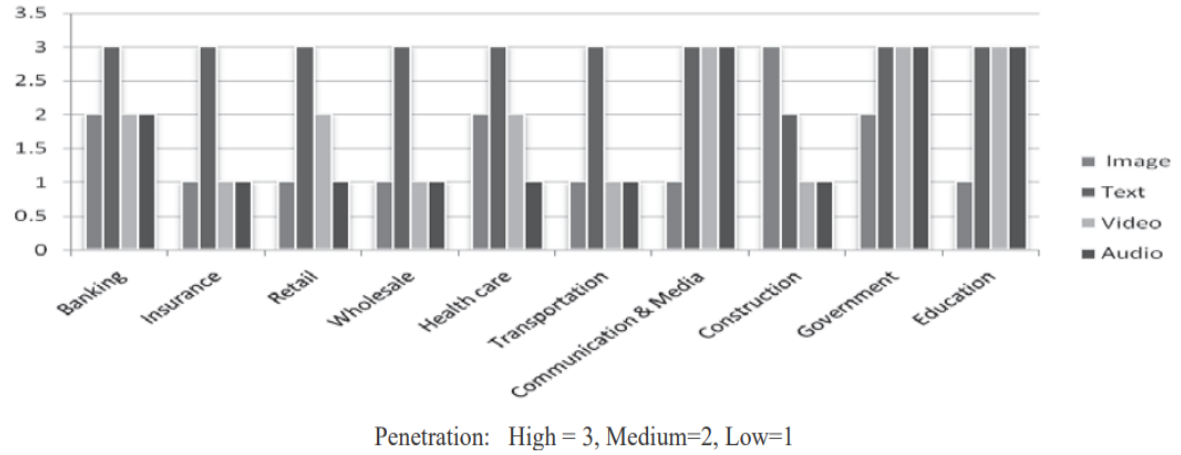
ABSTRACT

Big Data is a new idea that covers cutting-edge methods and technology for analyzing huge volumes of complicated information produced at different speeds and from diverse sources. Data mining methods are proving to be very useful in the field of Big Data Analytics (BDA), since dealing with large amounts of data poses significant difficulties for applications. The capacity to extract valuable information from massive databases is known as big data analytics. The significance, difficulties, and uses of Big Data in many areas, as well as the various methods utilized for Big Data Analysis utilizing Data Mining techniques, are discussed in this paper. The results of this study provide scholars with important information about the major trends in Big Data research and analysis utilizing various analytical domains.

KEYWORDS:*Big Data, Big Data Analytics, Big Data Application, Data Mining.*

10. INTRODUCTION

In our digital age, analysts have access to massive quantities of data. Big Data is a phrase used to describe a collection of unstructured, semi-structured, and structured information that are challenging to gather, manage, process, or analyze using traditional database software tools and technologies due to its volume, complexity, and pace of development. Text, video, picture, music, website log files, blogs, tweets, location information, sensor data, and more formats are used. Smart and scalable analytics services, programming tools, and apps are required to extract valuable information from such large datasets. The data comes in a variety of forms, including audio, video, pictures, and text, and it varies by industry. Text data is handled by the banking, insurance, and health-care industries. Audio and video data are heavily influenced by communication and media. Fig. 1 demonstrates how, based on the kinds of data produced and stored, there are differences in the quantity of data stored in various sectors.



Penetration: High = 3, Medium=2, Low=1

Fig. 1: Various sectors produce and store different kinds of data.

Data mining, also known as Knowledge Discovery in Databases (KDD), is an analytical technique used in a variety of fields to find meaningful connections between variables in big data sets. Analyzing large amounts of data in a short amount of time may lead to new insights and theoretical ideas. Big data has the potential to help businesses improve their operations and make quicker, more informed choices.

Data mining is the process of examining and analyzing large amounts of data in order to uncover patterns in big data. The methods were derived from statistics and artificial intelligence (AI), with a dash of database management tossed in for good measure. Data mining usually has one of two goals: categorization or prediction. The goal of classification is to organize data into groups. A marketer, for example, may be interested in the characteristics of individuals who reacted to a promotion vs those who did not. There are two types of classes. The goal of prediction is to forecast the value of a continuous variable. A marketer, for example, may be interested in forecasting who would react to a campaign.

11. LITRATURE REVIEW

This part includes a thorough assessment of the literature from a variety of publications, academics, and other online sources. It is split into two halves. The first section is an overview of Big Data's significance, difficulties, and applications in different areas. The second section covers the various methods to Big Data Analysis and their results using various Data Mining techniques.Wei Fan et al. provided an overview of big data mining in 2012, including its current state, debate, and future predictions [1].Kauret al. discussed a variety of Big Data problems[2]. They also discussed how Big Data analysis may help address certain operational, financial, and commercial issues in aviation that were previously intractable due to economic and human resource limitations.

S.Vikramet al. demonstrated the five aspects in which big data varies from ordinary data: volume, velocity, variety, value, truth, and complexity[3]. They discussed how large data systems are handled using the Hadoop framework. The authors also focused on the difficulties that businesses must confront when dealing with Big Data, such as data privacy, search analysis, and so on.D. Agarwal published a thorough research on data mining, models, issues, and applications in 2013 [4].D. Kishor proposed changing the fundamental concept of Big Data from 3V to 3C in order to better explain Big Data analytics using mathematical and statistical methods[5].In 2014, R Gupta et al. presented an overview of big data, its significance, big data technology, and how big data can be used to self-organizing websites, which can be extended to the area of advertising in businesses[6].

Big Data's content, scope, techniques, privacy, security, samples, benefits, and difficulties were all discussed by S. Sagiroglu et al[7]. They discovered that the difficulties were not only in collecting and managing data, but also in extracting valuable information from that data.In 2014, Xindong Wu et al. proposed the HACE theorem, which defines the characteristics of the Big Data revolution and offers a Big Data Processing model from a Data Mining perspective [8].Healthcare, networking security, market & business, education system, communications, and other real-time uses of big data were given by the authors Sabiaet al[9].B. Thakur et al. reviewed several kinds of big data in 2014, as well as major difficulties in big data management and analytics that emerge from the nature of data, which is vast, varied, and changing [10].In July 2015, the author Vatsal Shah examined huge amounts of unstructured data in the form of video and proposed a solution utilizing the Hadoop platform [11].

12. DISCUSSION

12.1. Big Data:

Big Data encompasses not just a huge amount of data, but also additional characteristics that set it apart from the notions of "extremely big data" and "massive data." In reality, there are many definitions of Big Data in the literature. “Big Data technologies represent a new generation of technologies and architectures intended to cheaply extract value from extremely large quantities of a broad range of data, by allowing high-velocity collection, discovery, and/or analysis,” according to the International Data Corporation (IDC). Big Data is defined by the McKinsey Report as "data sets that are too large for traditional database software tools to collect, store, manage, and analyze."

The three Vs, or Volume, Variety, and Velocity, are often used to characterize Big Data. The size of the data is represented by the volume. Velocity refers to the rate at which real-time data is generated and delivered. Because data originates from a variety of sources, as illustrated in Table 1, the data becomes too large.

TABLE 1: DIFFERENT TYPES OF BIG DATA & ITS SOURCES

Data Types	Sources	Formats
Structured	Business Applications such as retail, finance, bioinformatics etc.	RDBMS, OLAP, Data warehousing
Semi-structured	Web Applications such as web logs, email, webpages	XML, CSV, HTML, RDF
Unstructured	Images, Audio, Video, Sensor data, Blogs, Tweets etc.	User generated text content

The following Big Data definitions offer a collection of tools for comparing Big Data to conventional data analytics. Table 2 summarizes this comparison using the 3Vs (Volume, Velocity, and Variety) dimension.

TABLE 2: COMPARISON OF BIG DATA AND TRADITIONAL DATA

Characteristics	Big Data	Traditional Data
Volume	Terabyte, Petabyte, Exabyte	Gigabyte
Velocity	More rapidly	Per hour, day
Variety	Structured, Semi-structured or Unstructured	Structured
Data integration	Difficult	Simple
Data access	Real time or batch	Interactive
Source of data	Fully distributed	Centralized

The study of Big Data is at the heart of contemporary research and industry. Because a large quantity of data is produced from a variety of heterogeneous sources, storing, extracting, transforming, and loading it becomes challenging. According to a recent study, Google receives over 4 million search queries per minute, e-mail users send over 200 million emails, YouTube users upload 72 hours of video, Facebook users share over 2 million pieces of content, Facebook processes 350 GB of data per minute, more than 570 websites are created per minute, and Twitter users send 277,000 tweets per minute. According to estimates, the produced data constituted approximately 5 exabytes until 2003, 2.7 Zettabytes until 2012, and is projected to grow fourfold by 2016. Astronomy, social media/entertainment and networking sites, life sciences, healthcare, video surveillance, government data, sensor technologies and networks, mobile devices, and other fields all have large datasets.The Fig. 2 shows the data in Exabyte (EB) for the year 2005-15[12]. The quantity of data was rapidly expanded throughout this time owing to the major contribution of Big Data Analytics, as seen in this graph from 2005 to 2015.

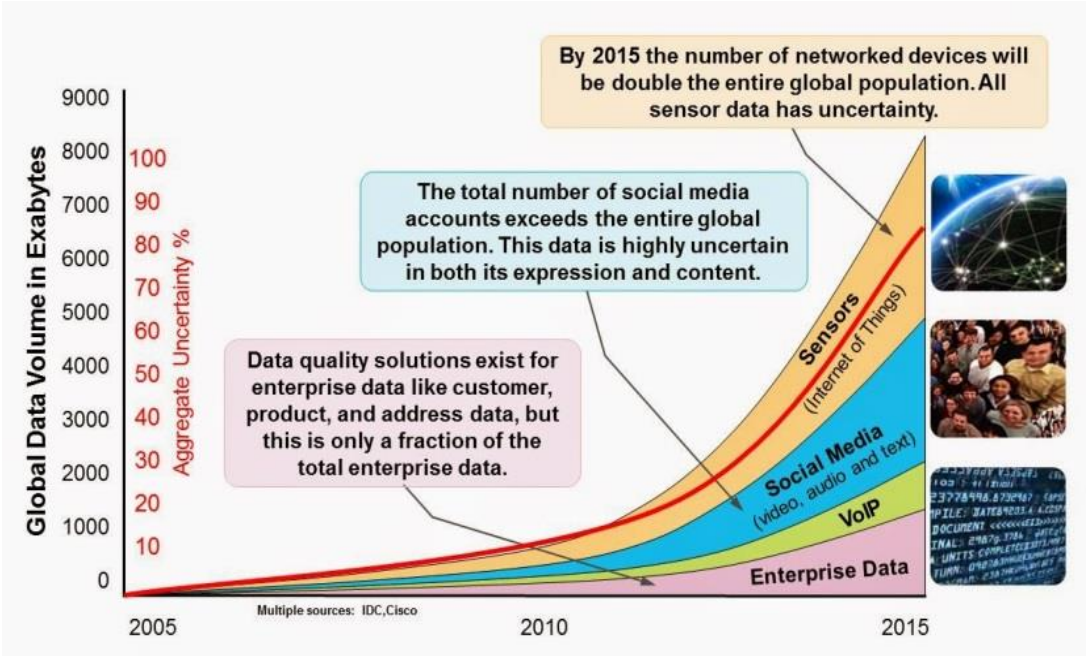


Fig. 2: Illustrates exponential data growth[12]**.**

Several difficulties that businesses or media must confront when dealing with Big Data include capturing Big Data, its length, storage, sharing, analysis, display of enormous data, and, of course, the most essential technology. For this, new architecture, algorithms, and methods for implementation are required. It also requires technological expertise. As a result, specialists are required to deal with Big Data using this new technology. Technical Challenges, Data Management and Sharing, Privacy, Security and Trust, and Misuse of Big Data are all issues that must be addressed while analyzing Big Data.

12.2. Data Mining:

Because there is a lot of data out there with a lot of hidden knowledge, data mining has become a hot topic in the information business. Indeed, we might argue that data mining is a relatively recent scientific study topic in the fields of statistics, machine learning, database management science, and visualization that aims to find and display information in a way that humans can comprehend. The goal of data mining is to extract hidden information from huge amounts of data. This information may assist and support organizations in making better and more informed choices.The potential for data mining algorithms to generate millions of patterns and rules is enormous. Knowledge is represented as an intriguing pattern. The discovery process may be guided by objective or subjective measures of pattern interestingness. There are a variety of common models that may be utilized to solve various data mining issues. Among them are Nave Bayes, Decision Trees, Neural Networks, Support Vector Machines, and K-means.

12.3. Big Data Analytics & Process Model:

Big Data Analytics is a tool that allows businesses to analyze huge amounts of data in order to find patterns and other valuable information. The quantity of data has grown rapidly over the last decade, from 2005 to 2015. This is due to the substantial contribution of Big Data Analytics. The following are examples of technical advancements in Big Data storage, processing, and analysis:

- In recent years, the cost of storage and CPU power has dropped dramatically.
- The creation of new frameworks, such as Hadoop, that enable users to take use of distributed computing systems capable of storing huge amounts of data and processing it in a flexible parallel manner.
- Datacenters and cloud computing's flexibility and cost-effectiveness for elastic processing and storage.

The Process model for Big Data analytics is the focus of this section. The entire model is split down into two sub-processes: data management and analytics, which are further separated into five phases as shown in Table 3.

TABLE 3: PROCESSES FOR EXTRACTING INFORMATION FROM BIG DATA

Big Data Processes	
Data Management	**Analytics**
1. Acquisition & Recording 2. Extraction, Cleaning & Annotation 3. Integration, Aggregation & Representation	4. Modeling & Analysis 5. Interpretation

TABLE 4: TAXONOMY OF BIG DATA ANALYTICS

Analysis Domain	Characteristics	Approaches	Techniques	Source of Data
Structured Data Analytics	Structured records, less volume and real time.	Statistical Analysis	Statistical Machine Learning. RDBMS, OLAP, Data Warehouse	Business & Scientific Data.
Text Analytics	Language dependent, Unstructured, Semantic, Rich Textual.	Text Mining, Opinion mining or Sentiment Analysis, Summarization, Question Answering System, Natural Language Processing (NLP).	Clustering, Neural Network, SVM, Decision Tree, Naïve Bayes	Emails, logs, Blogs, Twitter, Facebook, Webpage, Corporate documents, Government Rules and Regulations etc.
Web Analytics	Integration of Text and Hyperlink, Symbolic, Metadata	Web Content Mining, Web Usage Mining, Web Structure Mining	Classification and Clustering.	Various Web Pages
Multimedia Analytics	Collection of Audio, video & image	Indexing & Retrieval, Summarization, Error detection, annotation	Multimedia annotation, Video Summarization, audio Summarization	User generated multimedia, surveillance, healthcare media, corporation produced multimedia.
Mobile Analytics	Fragmented data, person specific	Monitoring	Location based mining	Mobile phone applications, sensors

The most crucial step of the Big Data Process model is data analysis. This model's aim is to derive valuable insights and conclusions that will aid in decision-making. The goal of data analytics is to collect as much information as possible that is relevant to the topic at hand. The researcher discovered that the produced data is separated into different areas of Big Data applications in Big Data Analytics. Structured Data Analytics, Text Analytics, Web Analytics, Multimedia Analytics, and Mobile Analytics are a few of them.Table 4 highlights all five kinds of Big Data applications, which are grouped by data type and include data features, various methods and techniques, and data sources. Data analytics deals with information about a phenomena acquired via observation, measurement, or experimentation.

13. CONCLUSION

In the past decade, the exponential increase in data capacity and complexity has prompted much study in the area of big data technology. We have attempted to synthesize the current literature review year by year in the field of Big Data and its analysis using various analytics methods in this article. Text analytics, which is regarded as the next generation of Big Data, is now widely acknowledged as a mainstream method of extracting valuable information from millions of opinions posted on social media. Because of the strong interest in real-time data of rich picture and video material, video, audio, and image analytics techniques have scaled with advancements in machine vision, multilingual voice recognition, and rules-based decision engines. They are possible answers to a variety of economic, political, and social problems.Our future work will mainly concentrate on the Big Data analytics method mentioned above, which will be implemented utilizing different data mining approaches.

DIRECTION OF TALENTED AND TALENTED STUDENTS FOR RESEARCH IS AN IMPORTANT FACTOR IN THE DEVELOPMENT OF SCIENCE AND PRODUCTION

Barno Nazarova*

*Associate Professor,
Candidate of Pedagogical Sciences,
Director of the Syrdarya Regional Center,
Retraining and Advanced Training of Public Education,
UZBEKISTAN

ABSTRACT

The introduction of a two-tier system in higher education, the introduction of training in specialties is the current implementation of the "National Training Program". At the same time, the training of talented specialists in accordance with the requirements of the state, society, science and industry is extremely important. The purpose is to find and train talented and gifted students, to develop their research skills, to encourage them to address pressing issues in society, science and industry, to develop the intellectual and scientific potential of the state and society of Uzbekistan.

KEYWORDS: *Talented and Gifted Students, Education System, Educational Process, Science and Production, Creative Approach, Students with Talent and Creative Potential, Talented And Targeted Training Of Gifted Students, Selection Of Gifted Students.*

INTRODUCTION

The process of identifying and selecting talented and gifted students, working with them individually and directing them to effective research on the basis of a creative approach of young people by the order of the Ministry of Higher and Secondary Special Education No. 137 of 1998 It is organized on the basis of the approved "Regulations on the search, identification and targeted training of gifted students" and the normative documents developed in the educational institution on the basis of these regulations. This process involves the following steps:

-Search, identification, discovery of talented and gifted students;

-Realization of their inner intellect and potential through targeted training of talented and gifted students;

-Targeted orientation of students with special scientific talent and creative potential to research activities;

- creating the necessary conditions for students to conduct research, expanding the volume of scientific and methodological resources;

- Supporting the scientific aspirations, creative pursuits and material and spiritual stimulation of talented and gifted students.

It is recommended to identify and select talented students in the following order:

- to hold a competition of gifted students at the end of the academic year, mainly among students of 1-2 courses, in case of interest and desire of 3rd year students;

-Orientation of gifted students from the 2nd year to research and development on an interesting and topical topic, taking into account their scientific interests and inclinations;

-Identification of talented and gifted students involved in research, development of selection criteria and standards;

- to study and evaluate the creative abilities of students, to invite them to the membership of the Council of Young Scientists on the basis of specially prepared tests, practical and theoretical assignments;

- Organization and holding of competitions for gifted students;

- Identify the potential and intellectual potential of gifted and talented students using pedagogical and psychological research methods.

Scientific and creative work with gifted and talented students, identified and selected on the basis of special competitions, can be organized in the following forms:

- Involve students in conducting research on interesting and topical scientific topics in the framework of the main research problems of the department under the scientific guidance of experienced specialists;

- To teach students to organize and plan research on a selected scientific topic, to develop in them the skills of preparing scientific articles and reports on the basis of preliminary findings of practical and experimental work;

- Involve them in participation in fundamental, practical and innovative projects implemented through the activities of schools of young scientists, scientific communities, as well as scientific laboratories;

-Organization of training courses on the basis of special plans and programs for in-depth study of foreign languages, information technology, history of Uzbekistan and the works of the President;

-To prepare and ensure their participation in inter-university, national and international competitions (Olympiads, competitions, conferences, etc.);

-To send students to educational institutions of developed countries for training and research trips.

The Young Scientists Council may make a number of recommendations to the administration based on the results of its work with talented and gifted students. Including:

-Organization of scientific seminars for students on the basis of scientific results of research, selection of reports;

-To closely assist students in publishing small scientific and creative materials based on the results of their scientific and creative work in the form of books and collections;

-Rewarding and encouraging the work of talented and gifted students and their supervisors, their special achievements, their candidacy for state awards, various contests and competitions, work in scientific and public organizations of the university. To recommend

The main activity of the School of Young Scientists, which operates under the departments of pedagogical universities, is aimed at attracting talented and gifted students to research, the formation and development of their scientific outlook. Therefore, it is necessary to provide additional education to talented students through the clubs organized by the School of Young Scientists. Clubs and their leaders play an important role in engaging students in research. The quality of training of scientific and pedagogical staff through higher education institutions often depends on the effectiveness of the club leader in organizing the work of directing students to scientific activities.

The main object and subject of the circle leader's activity is the student. The leader of the circle is required to take a creative approach to the organization of student activities. At the same time, the leader of the circle must achieve the student's recognition as an ideal person with scientific potential. The leader of the club has a responsibility to be an exemplary, exemplary teacher. This requires him to have professional knowledge, skills, abilities and scientific potential, as well as high human qualities, morals and a high level of culture.

In order to develop research skills in future teachers, the club leader is required to perform the following tasks:

1) Have a complete knowledge of the scientific and creative abilities of each student involved in the circle;

2) To be able to correctly select from the group of students students with research skills who can engage in research activities;

3) Be able to direct students in the group to work with scientific resources;

4) Be able to focus the talents, potential and interests of students in the group on solving specific science problems;

5) Individual work with each student on a specific scientific problem;

6) Ensuring pedagogical cooperation and communication of students with science teachers;

7) Creating opportunities for students to develop research skills;

8) Comprehensive encouragement and support of students' research abilities;

9) Creating a positive scientific environment among group members;

10) Active promotion of students' scientific achievements among the public;

11) To educate students on the principles of devotion to scientific work, love of certain sciences, honesty in science, perseverance;

12) To establish strong scientific ties between students and various scientific societies, the youth social movement "Kamolot", etc.

Students should be taught to analyze scientific phenomena and approaches independently, and to think critically about a particular scientific concept. Therefore, an important condition for the involvement of students in scientific activities is to equip them with existing scientific problems and practical and theoretical knowledge aimed at their solution, modern scientific information and the conditions for their solution. This requires the gradual expansion of the scope of scientific research, the formation of students' scientific outlook and thinking through the constant introduction of new scientific approaches.

Of particular importance are the programs developed by club leaders to promote student research. Such programs provide practical assistance to students in conducting their research and conducting research in a systematic manner.

The study of historical and scientific heritage and its use in the educational process will lay the foundation for the search and formation of young researchers in the future on the basis of "small scientific schools" in higher education, resulting in the creation of new modern scientific schools. Opportunities arise.

In the development of educational and scientific schools in the Middle Ages al-Khwarizmi, Mahmud Chaghmini, al-Bukhari, al-Termizi, al-Farghani, ar-Razi, Farabi, Abu Bakr al-Khwarizmi, al Pedagogical and didactic views of such great scholars as Beruni, Ibn Sino, Yusuf Khas Hajib, Ahmad Yassavi, az-Zamahshari, SulaymanBaqirgani, Mahmud Kashgari, Sheikh NajmiddinKubro, JaloliddinManguberdi, Ahmad Yugnaki, Pahlavon Mahmud, BahovuddinNaqshband worth noting. Consequently, the legacy of the named scholars still plays an important role in improving the educational process and technology.

The legacy of our ancestors is rich in information about the development of science and the individual, the opportunities for the development of intellectual potential. Finding ways to use this heritage effectively in modern education is a pressing issue. Educating young people in the spirit of national values and traditions, directing them to the right choice of profession, deciding on high human qualities, explaining the role and importance of scientific schools based on the traditions of "teacher-student", it is especially important to cultivate a sense of pride in the scientific and intellectual potential of our ancestors. To do this, every student at the university should be aware of the unique and rich historical heritage of our characters.

Experience has shown that the reorganization of science circles in accordance with the requirements of the time and social order, to focus on the issues of broader expression of the achievements of a particular science in the content of future-oriented modular training and attract the attention of young scientists. it is necessary to For example, the small school of pedagogical professionalism established at the Department of Pedagogy and Psychology of the Faculty of Pedagogy of Gulistan State University combines the circles "TafakkurGulshani", "Pedagogical Technologies" (headed by senior teacher O. Suvonov). On the basis of a special questionnaire on the subject of pedagogy, schoolchildren, academic lyceums and university students in the system

of continuing education are selected. The advantage of the "small school" over the school clubs is that the lessons are conducted in a non-traditional way: in the form of discussions, didactic and role-playing games, as well as non-traditional educational lessons. It develops students' research skills, creates full conditions and freedom for each member of the small school to express themselves in scientific and creative activities.

Science clubs organized within the departments of higher education institutions usually operate on the basis of a specific program, involving students of the course and faculty. The activities of the reorganized science circles at the department on the basis of period and social order are mainly aimed at solving a wide range of problems, including general secondary education, secondary special, vocational education and higher education. Pupils and students of educational institutions, and even pedagogical staff are widely involved. For example, 17 out of 40 participants of the "Small School" organized by the Department of "Pedagogy and Psychology" of Gulistan State University are students and teachers of Gulistan and surrounding educational institutions. Based on the main research problem of the department "Theory and practice of shaping the professional culture of the future teacher", scientific and creative research is conducted in 4 areas. Each direction is supervised by a leading specialist of the department. Preliminary results of the research will be discussed in detail with the participation of members of the circle. Conclusions will be made on the continuation of the study on the results of the positive feedback, and on the retraining of the research on the results of the objection.

It is important to pay close attention to science in the work of the circle. Because on the basis of scientific conclusions the necessary knowledge and concepts are formed. To do this, it is necessary to study the many sources and identify, expand the information contained in it, to involve students, masters, graduate students and professors in the education system to adapt them to education. Efforts should be made to solve problems together.

In accordance with the "National Training Program" in the education system of the republic, a lot of work has been done to introduce modern pedagogical and information technologies in the educational process, to ensure the continuity of educational content. In order to study and solve the problems of continuing education, it is advisable to establish "Small Schools" under the departments, which are part of the "Small Academy". Such "schools" include science circles based on the traditions of "teacher-student" and, based on the requirements of the time, provide scientific and methodological cooperation between general secondary, secondary special and higher education. It is a structure that studies the current problems of the process, which will have the opportunity to conduct research within the School of Young Scientists. Therefore, it is necessary to study, clarify, supplement the historical data on the research problem, as well as to identify and highlight the issues that have not yet been fully explored. The implementation of the results in the educational process will be the basis for the modernization of pedagogy in the country and the development of its new branches, as well as the creation of new educational technologies.

In the state program for the development and perspective of pedagogical science, pedagogical science as a priority area of science in the Republic of Uzbekistan serves the development of the independent state and society of Uzbekistan, educational models and technologies based on new pedagogical theories of continuing education. The need to increase the effectiveness of training

on the basis of equipping with weapons, the need to determine the goals, objectives and content of the activities of youth organizations in this regard.

ABSTRACT

This article provides information which is paid attention to the education system of the Republic of Uzbekistan and new reforms in the field of education management. In particular, the management system of general secondary education includes views on its composition and the responsibilities of its representatives, as well as on the experience of concrete and effective reforms to be implemented in this area. The measures taken in our country in the field of education until 2030 prove the importance of the future in the development of the country. New suggestions and comments were made on school management, which is the basis for the organization of the educational process.

KEYWORDS:*Manager, Education Management, Management System, Model Schools, MPE (Ministry Of Public Education), Education System Management Strategy, Reform, Education Quality, Teacher Training Institutes.*

INTRODUCTION

The main task of the education system is to provide our youth with in-depth knowledge in accordance with world educational standards, to educate them in the spirit of love for the Motherland, loyalty to the ideas of national independence. In turn, requires the heads of educational authorities, institutions and educational institutions to be organizers and entrepreneurs, highly educated and highly cultured.

It is well known that most secondary school principals are among the most hard-working public educators. At the same time, they face many challenges throughout their careers. There are, objective and subjective reasons for this situation. The main ones are:

- Poor knowledge of the theoretical foundations of education management;

- Inefficiency of school internal management;

- Failure to take into account the human factor in school management;

- Preservation of paperwork and command-based style;

- The division of labor between school leaders does not work well in practice;

- Neglect of professional development;

- Staff turnover;

- Inefficient use of time, etc.

The following are some of the key issues in school management that are key areas of governance. At the current stage of development of the secondary school, it is a difficult and responsible task to lead it. School internal control:

• It is a comprehensive study and analysis of the educational process in accordance with the goals set by the team.

• Regular, well-thought-out monitoring will help to identify and consolidate successes and prevent shortcomings in the work of the pedagogical team.

• School internal control disciplines teachers as well as school leaders. This work should be planned, regular, goal-oriented, complex, and cover all aspects of the educational process.

Improving and democratizing the management culture of managers in secondary schools is one of the important requirements of the modern market economy. It should be noted that in the current period of reforms, the management and administration of the economy is based on constitutional rules and scientific principles. Forms and methods of school management can change and improve at each stage of economic development of our republic in accordance with the tasks to be solved by society. However, at all stages of economic development of our republic, especially during the current reforms, the rules and content of public education management remain important. Therefore, proper organization of the school's internal manager is one of the most important requirements of our time. We consider it appropriate to pay special attention to these rules of governance.

In accordance with the decree of the President of the Republic of Uzbekistan dated September 30, 2017, the management system of the Ministry of Public Education has been improved, the main tasks and areas of activity have been identified. The President instructed to increase the salaries of teachers, their status in society, to provide them with social and legal support. It was emphasized that one should not be involved in activities that are not. The task is to create a special legal service to protect the rights of teachers. "The quality of general secondary education needs to be raised to a new level. State education standards and curricula need to be revised based on what children need to know in each classroom. There is a need to create and publish textbooks on the basis of the most modern methods, to strengthen the areas of technology, engineering, mathematics, art, foreign languages in schools, to re-equip laboratories in this area. It is also important to ensure integration with the pre-school and higher education systems,"saidShavkatMirziyoyev.

Review of the requirements for principals and deputy principals of secondary schools, the appointment of persons with real managerial skills to this position, the appointment of deputy directors for spiritual and educational work Special attention was paid to the financing of the public education system. It was noted that in the formation of the state budget for 2019 it is expedient to increase funding in this area, as well as to establish a special fund under the Ministry of Public Education to attract highly qualified specialists. In addition, the widespread introduction of information and communication technologies in the education system, the disposal of extra-budgetary income of schools, the establishment of a system of internal collective control in schools. The meeting focused on issues such as the development of school rankings in order to increase the number of model schools. In the Republic of Uzbekistan, the

education system is organized as a whole, and its form of government is centralized on the basis of commonality. The main basis of governance is the effective organization of education.

The education system of the Republic of Uzbekistan consists of:

• Governmental and non-governmental educational institutions implementing educational programs in accordance with state educational standards;

• Scientific and pedagogical organizations conducting research necessary for the functioning and development of the education system;

• Public administration bodies in the field of education, as well as enterprises, institutions and organizations under their management.

The education system of the Republic of Uzbekistan is unified and integrated.

Education in the Republic of Uzbekistan is carried out in the following forms:

• Preschool education;

• General secondary education;

• Out-of-school education;

• Secondary special vocational education;

• Higher education;

• Postgraduate education;

•teacher training and retraining.

Education authorities

The general management of the education system is carried out by the Cabinet of Ministers. The Cabinet of Ministers also directly manages the branches of a separate higher education institution, Tashkent Islamic University and internationally renowned foreign universities (MSU, Westminster University, etc.).

The powers of the Cabinet of Ministers of the Republic of Uzbekistan include:

• Pursuing a unified state policy in the field of education;

• Management of public education authorities;

• Development and implementation of educational development programs;

• Establishing procedures for the creation, reorganization and liquidation of educational institutions;

• Establishment of procedures for accreditation of educational institutions, certification of pedagogical and scientific personnel;

• Issuance of permits to educational institutions of other countries for the right to provide education in the territory of the Republic of Uzbekistan;

• Establishing and enforcing the procedure for recognizing foreign educational documents in accordance with the law;

• Establishment of state educational standards;

• Establishment of state educational documents and the order of their issuance;

• Determining the procedure for admission to educational institutions and the amount of state grants;

• Appointment of rectors of state higher education institutions;

• Establishing the procedure for transferring students from one accredited educational institution to another;

• Other powers provided by law.

The direct management of the education system in Uzbekistan is carried out by two ministries - the Ministry of Public Education (MPE) and the Ministry of Higher and Secondary Special Education (MHSSE).

MPE is responsible for the activities of preschool, out-of-school institutions and general education schools. MPE manages 5 higher education institutions and 16 teacher training institutes. The Ministry has regional, district and city departments of public education, which methodologically manage the activities of relevant educational institutions on the ground.

Sturucture of the Ministry of Public Education

- preschool education;
- general secondary education;
- District MPE
- Regional MPE
- City MPE
- out-of-school education;
- higher education;

Ministry of High and Vocational Education of Uzbekistan is the governing body of higher and secondary vocational education in the country.

The Ministry is accountable to the Cabinet of Ministers of the Republic of Uzbekistan.

- ❖ The system of the Ministry includes the Center for Secondary Special and Vocational Education,
- ❖ The Center for Higher and Secondary Special Education,
- ❖ The Center for Vocational Education Development and departmental universities.

Measures to improve the management system in education

Establishing priorities for the systemic reform of higher education in the Republic of Uzbekistan, raising the process of training highly qualified personnel with modern knowledge and high moral and ethical qualities to a qualitatively new level, modernization of higher education , in order to develop the social sphere and the economy based on advanced educational technologies:

The concept of development of the higher education system of the Republic of Uzbekistan until 2030 has been created. According to it, the "Roadmap" for the implementation of the concept of development of the higher education system of the Republic of Uzbekistan until 2030 in 2019 has been developed. The Concept of Development of the Higher Education System of the Republic of Uzbekistan until 2030 (hereinafter - the Concept) Ensuring strong integration of science, education and industry based on the needs of the social sphere and the economy In order to improve the quality of education, training of competitive personnel, effective organization of scientific and innovative activities, development of international cooperation, as well as the

President of the Republic of Uzbekistan dated July 11, 2019 No PP-4391 "On measures to introduce new principles of governance in the education system."

The concept defines the strategic goals, priorities, objectives, medium and long-term stages of development of higher education in the Republic of Uzbekistan and serves as a basis for the development of programs and comprehensive measures in this area.

School management is also strategized on the basis of the above-mentioned structure, that is, it is carried out in a well-defined, clear plan and direction. A school charter has also been developed, which includes the following rules.

School management is based on the principles of democracy, transparency and self-government. The school community works closely with parents, neighborhood committees, and the general public.

The school pedagogical council is the highest governing body of the school. The school principal is the chairman of the pedagogical council.

The pedagogical, methodical, guardianship councils and the parents' committee of the school are formed and function on the basis of the relevant Regulations approved in accordance with the orders of the Ministry of Public Education.

The school principal is directly in charge of the school's educational process and day-to-day operations. School principal:

The school director directly supervises the educational process and the day-to-day activities of the school, organizes the educational (educational) work in the school, provides the administrative-economic (production), financial work of the school, creates a procedure for compliance with safety standards and regulations in the school.

The school principal shall be appointed and dismissed by the head of the relevant public education department upon the recommendation of the head of the city public education department. The school principal reports directly to the head of the city's IEP. The Deputy Director for Educational Affairs, in cooperation with the school principal, organizes the educational process in the school, provides methodological guidance to the school teaching staff, ensures compliance with safety standards and regulations in the educational process. provides, reports on educational work and organizes work on general compulsory education.

The Deputy Principal for Academic Affairs reports directly to the school principal.

Directly to the Deputy Principal for Academic Affairs

1) Teachers; 2) students; 3) Laboratory staff.

The Deputy Principal for Academic Affairs shall, within the scope of his / her authority, perform the following duties:

The activities of the teaching staff include daily and future planning. Coordinates the implementation of curricula and programs for teachers and other educators. Organizes and coordinates the development of the necessary teaching materials. Regularly monitors the quality of the educational process and the objective assessment of the results of educational training of students, the work of clubs and electives; The school attends classes and other types of classes conducted by teachers (at least 180 hours during the school year), analyzes their form and content, informs teachers of the results of the analysis. and conduct their work. Organizes educational work for parents, receives parents (substitutes) on the organization of the educational process. The educator assists the staff in mastering and developing new (innovative) programs and pedagogical technologies; compiles schedules of classes and other types of educational activities, ensures quality and timely replacement of classes of temporarily absent teachers,

missed and replaced by another teacher keeps a log of lessons. Ensures the timely preparation of prescribed reporting documents, monitors the correctness and timeliness of class journals and other documents by teachers.

The educator participates in the selection and placement of staff, organizes work to improve their skills and professionalism; supervises the work of methodological associations, improves their skills. Participates in the preparation and conduct of certification of teachers and other staff of the school; maintains, signs and submits to the school principal the timesheet of teachers and teaching staff. Organizes timely and quality certification of classrooms, workshops, gym and ancillary rooms with the participation of the Deputy Director for Administrative and Economic Affairs. Instructions on labor protection as well as the development of safety sections in the guidelines for practical and laboratory work and periodically reviewed at least once every 5 years. Deputy Director for Educational Affairs in collaboration with determines the methodology and procedure for teaching traffic, water and street behavior, fire safety rules, conducts testing of students' knowledge. Carries out administrative-collective control over the safety of use and storage of teaching aids and equipment, chemical reagents, visual aids, school furniture in cooperation with the trade union committee. Takes timely measures to remove artificial chemical reagents, training equipment and tools not provided for in the standard lists, including those installed in workshops, classrooms and other rooms without the appropriate permit, etc. suspends the educational process in the event of dangerous conditions for the health of staff and students in the rooms of the educational institution. At school, in life, in public places, teachers adhere to ethical norms that are appropriate to their place in society.

Deputy Director for Spiritual and Educational Affairs:

The Deputy Director for Spiritual and Educational Affairs shall be appointed and removed from office by the Head of the City Department of Public Education upon the recommendation of the Director.

The deputy director of the school for spiritual and educational work organizes out-of-class and out-of-school educational work with students, provides general methodological guidance on the educational process, conducts specific activities with students and ensures compliance with safety standards and regulations in extracurricular activities, provides guidance in collaboration with the neighborhood committee and other out-of-school organizations.

In conclusion, an educational quality of an institution is a graduater, not an educational service. The starting point for the formation of a quality management system should be the construction of a “model” of the graduaters of the educational process, which should be a combination of personal professional qualities that should be focused on the educational process: its content, teaching methods, forms of organization, methods of assessing and evaluating students' knowledge. However, it should be noted that the learning process is the foundation of the educational organization. At the same time, it cannot be separated from other types of activity: scientific, educational, methodological, and administrative.

Competitive personnel will be developed according to followed stricted accurate rules of the establishment. The organization of school management should be based on the full motivation of teachers, as well as the adoption of a disciplinary charter by each school, its transformation into a law of the school, and the exchange of views with parents on these rules in the educational process. - Working with mothers makes the educational institution a more effective management institution.

ABSTRACT

The use of conventional Internet protocols for living thing or thing-to-thing interaction in embedded networks is a straightforward interpretation of the phrase Internet of Things. The primary goal of the Internet of Things is to build a virtual footprint of all connected devices and people. It establishes a new means of communication between all things and humans, as well as between objects themselves. IoT allows us a new degree of connectivity. This article summarizes all of the IoT ideas and mechanisms. RFID systems, sensor networks, or intelligence technologies are all key technologies that allow IoT. The possible uses of these technologies are discussed, as well as the main research problems.

KEYWORDS:*IOT Technology,Internet RFID, Wireless.*

INTRODUCTION

In the area of wireless communication, a new paradigm known as "The Internet Of Things (IoT)" was developed many years ago. Kevin Ashton created this phrase in his demo in the year, and its significance has grown steadily since then. Incorporating Internet of Things (IoT) into embedded mobile transceivers in a broad variety of products would take information and communication technologies to a whole new level. The Internet of Things (IoT) is a critical component in corporate change. The concept of the Internet of Things was examined during the 20th Tyrrhenian workshop on digital communications. The Internet of Things (IoT) is defined as a network of different “things” or “objects” around us, such as sensors, mobile phones, and Radio Frequency Identification (RFID) tags that interact with one another and effectively perform their duties using a unique addressing system. To comprehend the Internet of Things, we must first comprehend the function of RFID technologies (used to identify or communicate with other devices).

Wireless Sensor Networks (which compose information gathering, processing, and transformation), intelligent technologies (to solve issues and initiate and regulate machine-to-machine interaction), and Nano-meter technologies are the mainstays of the Internet of Things

(to construct small devices in order to socialize the IOT applications). In the area of IoT, research is continually being done in order to make it more user-friendly and to improve the security of the data transmitted via it. In Japan, the Unique Identifier (UID) is the best architecture, as well as the EPC worldwide networks provided by Auto-Id labs are the finest in the sector. The primary goal of these organizations is toaims to create a system that uses RFID tags and wireless communications to link every item on a global platform known as the "Internet." The Electronic Products Code (EPC) is a unique identifier that is regulated by the RFID technology. In 2009, Palmisano, the CEO of IBM, presented an idea dubbed“Smart Planet” by incorporating sensors into all objects and other systems such as railroads, electricity grids, and other devices that interact with one another and other gadgets.clever architectural design The concept of "Sensing China" was first proposed in 2009[1].

In Wuxi, Jiangsu Province, a hub for sensor networks was established, which is a major supplier of science and technology patents in the country. The overall concept is11.1 billion RMB is a rough estimate. Other big nations have also begun research in this area in order to build stronger IoT infrastructure.IoT has been represented or defined from a variety of viewpoints, and as a result, IoT is explained in a variety of ways. The two terms "Internet" and "Things" are the primary reason for all of these different meanings. The term "internet" refers to a collection of networks and entities that are mostly made up of generic items.When you mix the terms Internet and Things; you get a whole new level of progress in the world of ICT. The phrase Internet of Things (IoT) refers to a global network of linked things with a unique EPC, or address. The most perplexing job in this system is identifying and storing the items that have been traded.information. As a result, a new notion of semantic viewpoint emerges in the IoT.CASAGARAS consortium presented an advanced method that is much superior than RFID's approach. The consortium's primary goals are twofold[2], [3].

- It supports IoT globalization, which allows us to link the virtual and physical worlds.
- Assists with current and future internet and network advancements.

Layer at the edge:

Embedded system, sensor networks, as well as other types of hardware are included in this hardware layer. The main data sensors that have been installed are among them. RFID tags, sensor networks, or embedded edge processors are all provided by these hardware components.

Layer of The Access Gateway:

This is where the initial stage of data handling takes place. It can conduct cross-platform communications as well as message routing, publishing, including subscribing.

Layer of middleware:

In bidirectional mode, this is the most important layer. It serves as a link between the hardware layer and the application layer at the top of the stack. It is in charge of essential tasks including device and information management, as well as data filtering, data aggregation, sentiment analysis, security systems, including information discovery.as well as the EPC (Electronic Product Code) information service and the ONS (Office of National Statistics) (Object Naming Service).

Application layer:

sits at the top of the stack and is in charge of delivering various IoT apps to diverse consumers. Manufacturing, logistics, retail, environment, public safety, healthcare, food and medicine, and other industry verticals may all have uses. With the maturation of RFID technology, a slew of new applications is emerging.will fall under the IoT umbrella.

Applications:

IoT allows items in our daily working or living environments to interact and comment on data gathered from their surroundings, allowing for a wide range of applications. IoT applications that are either immediately relevant or closer to our present living environments are divided into three areas.

Management of the Supply Chain:

In the Internet of Things, real-time information processing technology based on RFID and NFC is utilized. We can correctly overlook and handle real-time data, work-in-progress, and in-progress data.It is possible to acquire transit phases with accurate due dates. This would result in a more accurate prediction and an increase in the forecast. Out-of-stock items are automatically replenished, andInventory decrease might be feasible. It would just take a few days to implement these technologies, and they would operate with no safety stock. Transportation Automobiles, buses, and trainsSensors, actuators, and processing power will become increasingly common in taxis and road junctions. To actualize traffic, important data may be gathered.oversight and advice, assistance with depot management, and providing visitors with accurate transit information One of the most significant IoT applications is theTIG (Traffic Information Grid) is a traffic information grid that is deployed on the Shanghai Grid[4].

Disaster Preparedness and Response:

Natural catastrophes and unintentional disasters have become more common in recent years. RFID and WSN technologies play a critical role in predicting disasters and assisting with recovery when they occur. Residents in the surrounding region would have more time to prepare if they had timely access to pertinent information about dangerous environmental conditions.Prepare measures to mitigate the damage and reduce the number of victims as a result of the incident. WSN allows for the collection, processing, and transfer of data.Environmental data from the point of genesis of catastrophes to cities that may be in jeopardy. Authorities may then utilize this information to quickly evaluate urgent situations and arrange resources.

Unresolved Problems:

Standardization:

Despite significant efforts by scientific communities, European Standards Organizations (ETSI, CENELEC, CEN, etc.), Standardization Institutions (ISO, ITU), and global Interest Groups and Alliances (IETF, EPC global, etc.) to standardize the IoT paradigm, they are not integrated in a comprehensive framework. Efforts to standardize have centred on three main areas: RFID frequency, communication protocols between readers and tags, and data formats utilized on tags and labels. Major standardization organizations working with RFID technology include EPC Global, the European Commission, and ISO. The primary goal of EPC worldwide is to promote the global adoption of an EPC for each tag as well as associated industry-driven standards. The European Commission has made concerted efforts to define RFID technology and facilitate the transition from localized to global deployment.RFID uses for the Internet of Things ISO, on the other hand, is concerned with how to modulate, use frequencies, and avoid collisions from a technical standpoint[5].

Which is more important, policy or security?

Authentication or data integrity is the most important aspect of security. Due to a lack of suitable infrastructure and servers to send data between nodes, authentication is particularly difficult in IoT scenarios. Furthermore, objects have less resource to do complex calculations than PCs, PDAs, cell phones, and other devices. There have been a few proposals for authentication techniques, however they all have significant faults and are useless against man-in-the-middle

attacks. For data integrity solutions to function, an opponent must be present. It's difficult to change data in transactions without causing the system to malfunction. In the traditional information sector, the problem of data integrity has gotten a lot of attention. When RFID systems or sensor network are connected to the Internet, a new problem will arise. Sensor nodes or RFID tags are distributed over a wide area and spend most of their time there.Adversaries may tamper with data while it is being stored in the node or traveling across the network. Memory is encrypted to protect data from the first kind of attack. The bulk of tag technology solutions for sensor networks have been described[6].

Within the IoT technology stack, connectivity options are available

There are as many potential real-world uses of IOT. as there are connection methods to support them. Each communications method may provide various service enablement possibilities depending on the requirements of a particular IoT use case, with trade-offs between battery consumption, range, and bandwidth. If you're constructing a smart home, for example, you may want to connect your interior temperature sensors and heating controller with your smartphone so that you can remotely monitor and change the temperatures in each room based on your current requirements. The IP-based IPv6 networking protocol Thread, which was developed specifically for home automation environments, would be the preferred option in this situation.

With such a wide range of communication standards and protocols, one may wonder why new solutions are needed when there are already well-proven Internet protocols have been in use for decades. The reason for this is that current Internet protocols, including such Transmission Control Protocol/Internet Protocol (TCP/IP), are often ineffective and power-hungry, making them unsuitable for use in developing IoT technology applications. This section will provide a quick review of the most popular alternative Internet protocols designed specifically for IoT devices.

Governance:

In the IoT ecosystem, like in the current Internet, issues of "thin" legitimacy and a lack of adequate openness and accountability emerge. Because the Internet of Things (IoT) is more than just a buzzword, The Internet Governance ideas are no longer appropriate to be applied uniformly, since they are not an extension of today's Internet, but rather a networking of separate yet compatible systems.applied. Learning from Internet censorship, the idea of "multi-stakeholder governance" should be seen as the new way forward in favor of the participation of all stakeholders.the whole society Such a change calls into question the conventional notion of legitimacy and necessitates addressing the broad issue of who may be considered legitimate.

Because IoT technology has already established itself in our homes, public places, offices, and factories, and because of its rapid growth, the overused IoT slogan "everything that can be linked will be connected" seems to be getting closer to being our everyday reality. As a result, the important issue isn't when this will happen, but how the connections will be established to achieve maximum efficiency while maintaining essential characteristics like security and cost-effectiveness. With this in mind, a deployment including a large number of low-power, low-bandwidth devices would need the adoption of LwM2M, a lightweight protocol developed specifically for managing machines with limited resources. As a result, from a practical standpoint, the issue of success in the case of specific IoT applications seems to come down to selecting the right IoT technology from the wide variety of available options.

LITERATURE REVIEW

Zhang et al studied about The Narrowband Internet of Things (NB-IoT) is a new 3GPP radio interface standard intended for low-power wide-area networks (LPWANs). It can offer great coverage (20dB better than GPRS), low device power consumption (up to 10 years of battery

life), low delay sensitivity, huge capacity, and ultralow device cost. NB-IoT is thought to offer a lot of promise for Internet of Things (IoT) applications including smart meters, intelligent parking, precision farming, industrial automation, logistics pallet tracking, and intelligent buildings. There has been study into many elements of NB-IoT technology, but much of it has been focused on theoretical as well as simulated analyses, with little connection to an actual NB-IoT network. China Telecom, China Unicom, or China Mobile have been doing pre-standard NB-IoT technology trial work in certain regions since 2016. An in-depth performance assessment of NB-IoT in a real-world indoor setting is presented in this article. This research looked at whether the existing NB-IoT network can support connected devices and meet the needs of IoT applications in an indoor setting. Meanwhile, it looked at the network's limitations based on existing NB-IoT technology, particularly in terms of latency and packet delivery sizes[7].

Pinka et al. investigated the Internet of Things (IoT), which is now one of the most popular technologies. By 2020, it is predicted that there will be 50 billion Internet-connected gadgets. Smart cities and smart homes, for example, depend heavily on IoT phenomena, which use a broad range of sensors for data gathering, analysis, and subsequent actions. The article explains how Riga Technical University uses this cutting-edge and relatively new technology for instructional reasons[8].

Ahemd et al studied about the Internet of Things (IoT) has been a major breakthrough in Information and Communication Technology. Over 50 billion gadgets are expected to be connected to the Internet of Things in the next several years. The IoT network's security should be a top concern. From 2010 to 2016, we evaluated the security issues in the four levels of the IoT architecture, as well as the solutions offered. In addition, key security technologies such as encryption are examined in the context of the Internet of Things. Finally, we address security attack remedies on various levels of the IoT architecture, as well as future research areas within the IoT architecture[9].

Al Hogail et al. conducted research on the According to studies, trust plays an important part in consumers' decisions to embrace Internet of Things (IoT) technologies or services since it helps them overcome risk and ambiguity associated with them and increases their degree of acceptance and adoption intention. Nonetheless, research on the behavioral component that explain consumers' perceptions of IoT adoption are still lacking in the IoT literature, which focuses more on the technical side. The primary aim of this research is to look at the variables that affect customer trust and their impact on IoT adoption. A conceptual trust model has been developed that covers the main variables influencing trust in IoT technology adoption. Product-related factors, societal interference factors, and security-related factors are the three categories of variables that we believe will affect the degree of confidence in the model. This paradigm is verified by polling consumers' thoughts, which offer perspectives and comments on the variables that influence their confidence in technology. The model may help researchers dig deeper into the trust problems and build a reliable body of knowledge to drive IoT product development or marketing strategies that are tailored to the needs of consumers[10].

DISCUSSION

Many years ago, the "Internet of Things (IoT)" was created. This term was coined by Kevin Ashton in his presentation last year, and its importance has risen gradually since then. Incorporating Internet of Things (IoT) into integrated mobile transceivers in a wide range of goods will elevate information or communication technology to new heights. The Internet of Things (IoT) is an important part of business transformation. A simple meaning of the term Internet of Things is the use of traditional Internet technologies for living thing or thing-to-thing interaction in embedded networks. The Internet of Things' main aim is to create a virtual

footprint of all connected people or devices. It creates a new communication channel between all things and people, as well as between items themselves. The Internet of Things provides us with a new level of connection. This research, on the other hand, takes a comprehensive look at the topic. Technologies that are appropriate It is anticipated that, for the not future, the aim of achieving "Everyone will now be able to connect from anywhere and at any time. Anything is possible "should depend on cross-discipline or team members Previous work in comparable areas should be used as a starting point as a consequence, architectural guidelines must be adhered to. It was designed and launched in a global legal environment. Representation has a legitimizing effect only if the outcome is genuine. Reflects the value of the parties represented This concept, in addition to being equal, requires bargaining power and fair processes. Governance of the Internet of Things: Transparency, accountability, as well as public involvement in decision-making.

CONCLUSION

The state-of-the-art on the Internet of Things in this article, which covers a variety of definitions, enabling technologies, and various applications, as well as open research problems and initiatives.This study, on the other hand, offers a thorough examination of the subject. Technologies that are relevant It is expected that in the not-too-distant future, the realization of the goal of "from anywhere and at any time will now have access to connection for everyone. Anything "should rely on cross-discipline and collaborative efforts Previous work in similar areas as a result, architectural standards must be followed. Created and produced under a legal context that is worldwide. Only if the result is legitimate has representation a legitimizing impact. Represents the value of the represented stakeholders Aside from being equal, This idea requires negotiating strength and fair procedures.Transparency, accountability, and public participation in decision-makingGovernance of the Internet of Things.

ABSTRACT

Green wave energy is abundant in the seas and it is currently being utilized to produce power on a large scale. It may also be used to power a single beacon, buoy, or underwater vehicle. A wave energy converter (WEC) device is a kind of wave energy harvesting device that transforms the kinetic energy of waves into electrical energy. Its primary feature is mobility, and it can be directly built on different types of power supply equipment, with promising development possibilities. A floating type WEC is described in this article. With the assistance of a permanent magnet and an induction coil, this suggested device transforms the mechanical energy of the wave into electrical energy. The suggested technology is based on the electromagnetic induction concept (EMI). This method uses ferrofluids to decrease the damping of the magnets' motion while also amplifying the magnetic field. This system does not depend on hydraulics for energy conversion and can simply be moored to another offshore wind energy asset or to itself. The asset will be able to run 24 hours a day, seven days a week, reducing intermittency and ensuring consistent production all year. Despite the fact that previous study in this area has been conducted, there is a critical need for additional research in this field in the future.

KEYWORDS:*Energy Conversion, Electromagnetic Induction, Magnet, Wave, Wec.*

1. INTRODUCTION

The demand for electrical energy is exploding as a result of technology advances and an ever-increasing human population. Electrical power producing capacity must be expanded on a worldwide scale to meet the growing demand for energy. Currently, the majority of electricity generators depend heavily on fossil fuels. It is a reality that non-renewable energy sources such as coal, petroleum, and gasoline are depleting at an alarming pace. Carbon dioxide and other greenhouse gases are emitted by these sources, which are detrimental to the environment. According to projected findings, the average temperature of the earth's surface would increase by

1.4-5.8 degrees Celsius by the end of the century. Furthermore, based on previous decades, the warming rate is projected to be 0.02 0C each year. Solar, wind, hydropower, biomass, and geothermal energy are examples of renewable energy sources (RES) that may be utilized as a substitute for conventional fuels since they are readily accessible and do little to no environmental damage[1]. Figure 1 show the power generation from RESs.

Mechanical movement is created by oceanic waves in wave energy collecting systems. Waves are unpredictable in nature, which has an impact on wave energy devices. There are no rotating motions in the random mechanical movements. The random motion may be transformed into steady rotating movement with the help of auxiliary devices. However, the auxiliary devices are subjected to a more thorough examination due to their monetary cost, energy waste, and complicated upkeep. As a result, conventional wave energy harvesting systems are ineffective. To transform mechanical motions into electrical energy, a specific kind of equipment is needed in addition to the generator. The vast majority of these generators are linear generators (LGs) that work on the electromagnetic induction principle. For this aim, small-scale piezoelectric and triboelectric generators have recently been tried. Ocean wave energy (OWE) energy extraction is still in its early stages, and more study is needed before it can compete with wind and solar power facilities[3].

With the assistance of electromagnetic induction, the suggested method uses mechanical vibration of the wave to produce energy. Electrical energy may be effectively produced using vibrational energy. Vibrations are regarded unneeded in most areas, despite the fact that there are numerous sectors in which this kind of energy has been used in a more beneficial way. The fundamental concept of electromagnetic induction is used to accomplish this. Spring serves as a source of energy. When there are external factors present, such as ocean wave movement, vibrations are generated. The spring vibrates and expands or compresses, causing electric flux to be produced. Electromagnetic induction occurs as a consequence, resulting in electric voltage. The spring's mechanical strength is such that it does not break or collapse throughout the whole operating duration, even oscillating for long periods of time. It's also designed to be very sensitive to tiny vibrations. Vibration amplification springs are the name for these types of springs. They have sympathetic vibrations that are responsive to external oscillations. The vibration amplification spring is used to surround a magnet and move it in an upward and downward motion with great precision. As a consequence, electromagnetic induction occurs, resulting in electricity. This is the vibration power generating mechanism that is utilized in wave energy conversion (WEC)[4].

	Hydro power	Wind power	Solar PV	Bio-power	Geothermal power	Solar thermal	Ocean power
2017	10	8	1	0.5	0.05	0.01	0.001

2019	70	15	12	1	0.5	0.8	0.5

Figure 1: Illustrates the electric power generating capacity using different RESs[2]**.**

The proposed system converts wave mechanical energy from the ocean or any big water body into electrical energy by cascading WECs in series and parallel configurations. This WEC may also be used on any surface that generates continuous oscillatory/vibratory motion to generate an electric current that can then be converted to alternating current (AC) or direct current (DC) as needed depending on the experiment. The suggested system works on the concept of electromagnetic induction (EMI). Permanent magnets and an induction coil are used in the proposed system. EMF is induced in the coil by the motion of the permanent magnet produced by the wave. Ferrofluids are used in this system to decrease the damping of the magnet's motion and to amplify the magnetic field. This method produces continuous energy while using wave energy, addressing the intermittency issues that solar and wind power production systems have. The suggested system is a floating generating system that does not pollute the marine environment, thereby eliminating the disadvantages of existing marine power production systems [5].

2. LITTERATURE REVIEW

Faizal et al. discussed floating point absorber wave energy converter.Various wave energy conversion systems utilize different methods to convert wave energy to useable energy. Because of the changing incident waves, the generator's power output will fluctuate. The interaction between the wave structure and the incident waves causes changes in the incident waves, which affects the power output. The gadget must be sufficiently stable to avoid capsizing. When the incident wave frequencies match the device's inherent frequency, the point absorber will function at its best. Although the techniques for determining natural frequencies for pitching and heaving systems are given, this system is a fixed type with a more complicated power take-off [6].

Zhongyue et al. discussed a new adaptive reversing wave energy generating device that belongs to micro-sized wave energy generating device. The low speed and huge torque wave energy may be transformed into electric energy, which can be utilized for load and lithium battery charging, using the upper and lower absorber blade groups. For the features of the wave energy producing device, a finite element analysis of the blades is performed, and the experimental platform is constructed and validated via tests. The real output voltage curve of the wave energy producing device is produced based on the wave condition of 150mm wave height in various periods. The output voltage oscillates periodically due to the device's periodic oscillation. The output voltage fluctuates by two times in one period of device movement. There will be a period when the blades are not spinning between the device's upward and downward oscillations, and the output value on the voltage value will be 0. The water resistance of the blade, as well as the torque of the generator, contributes to this. To ameliorate this condition, it may raise the wave speed relative to the blade, or add quality to the outer wheel to increase the rotation inertia, and guarantee a sustainable blade rotation and a continuous power production process under the action of inertial force [7].

Matt et al. discussed the Oscillating Wave Surge Converter (OWSC) as a novel shoreline or near-shore WEC. A study of the performance of the shoreline oscillating water column led to the development of the idea. The OWSC is designed to tightly link with horizontal particle motion, allowing high amplitudes of working surface motion while reducing energy losses in related water particle movements. A potential shoreline and near-shore WEC is the Oscillating Wave Surge Converter. The tank testing that has been done so far has not been extensive, but it has been enough to show that the OWSC is more productive than an ocean wave converter (OWC) on the beach and Pendular. Furthermore, the OWSC should have lower construction costs than both a shoreline OWC and a Pendular, leading in a cheaper cost per unit of supplied energy, i.e. pence/kWh. In addition, many different OWSC implementations have been discovered, each with its own set of benefits and drawbacks[8].

Myin et al. discussed a Cross-flow turbine that will generate 100 kW output power from a head of 28 m and a flow rate of 0.5 m^3 /s. The rotating speed is 600 rpm, the specific speed is 95.39, the runner diameter is 340 mm, and the runner width is 416 mm for these heads and capacity. The runner's precise design drawings are also well shown in this article. Furthermore, the diameter and breadth of the runner are shown with different flow rate ranges of 0.2 to 1 m3 /s and head ranges of 10 to 50 m. As a result, selecting the appropriate runner's dimensions based on the matching head and flow rate is simple. The Cross-flow turbine is utilized in rural regions and places that are distant from the grid system for high demand energy. It may be utilized for low and medium head water using basic technology that can be developed and constructed locally using mostly local resources at a cheap cost utilizing simple technology[9].

3. ENERGY HARNESSING SYSTEM

An energy harvesting system consists of a module that floats on the surface of a wave-producing body and captures and transforms wave energy into electrical energy. To transform wave energy into electricity, the technique primarily depends on electromagnetic induction. The basic unit's output is a low-powered alternating current (AC) that is converted to direct current (DC). DC-DC converters will be used to smooth out the erratic DC current and convert it to a constant DC output, which can subsequently be converted to AC current using inverters.Figure 3 illustrates the schematic diagram of a single unit of the converter.

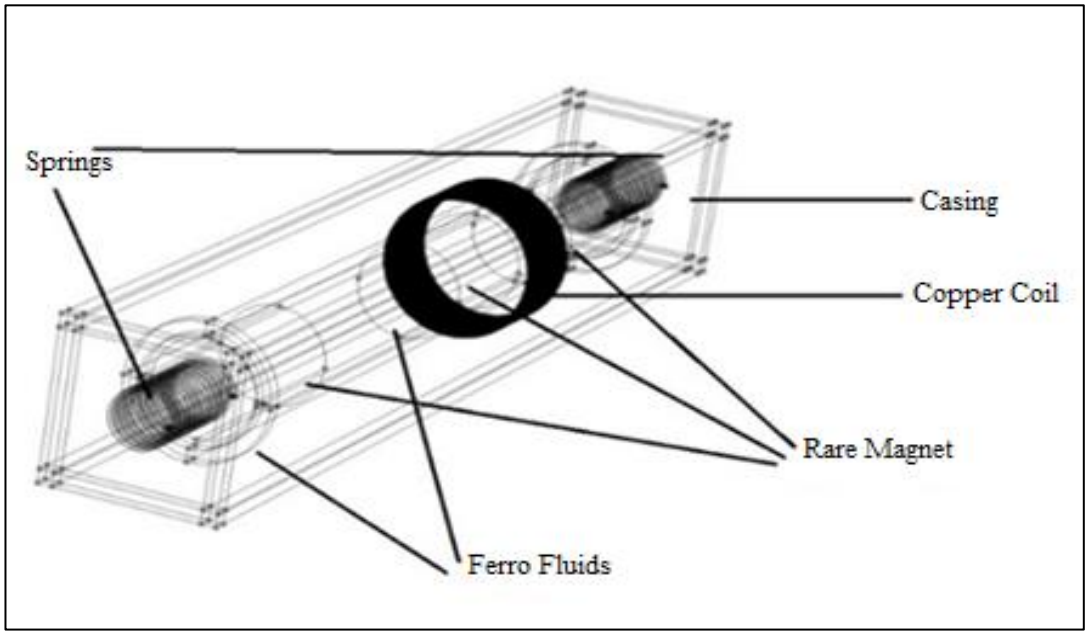

Figure2: Illustrates the schematic diagram floating energy harnessing module which generates EMF[10]**.**

Multiple units can be stacked together in series and parallel combinations to produce an output of 200W-400W unit that will have an approximate dimension of 30 in 30 in 10 in to make up a floating unit that can then be stacked to produce the utility-scale power output. This single unit has a power rating of 0.6-2 W.

3.1. Construction:

WEC is made up of a basic unit that is housed in the case shown in Figure 3. The casing should be non-magnetic and constructed of recyclable polymers if possible. Two springs, S1 and S2, are connected to the fixed hooks FH1 and FH2, which are part of the outer shell or encasing, in the basic unit. A glass closed tube is connected on both sides to springs S1 and S2 at hooks H1 and

H2, respectively. M1, M2, and M3 are the three magnets in the tube. At H1 and H2, M1 and M3 are secured and connected to the tube's closing two ends, respectively. Ferrofluids and M2 are free-moving components in the vacuum tube. Induction coils are wrapped around the tube to capture the relative motion of the magnet M2 and produce energy via electromagnetic induction. Depending on the length of the tube and the amplitude of the wave, there may be several coils. The basic unit's output is low-powered AC, which will be converted to DC.

3.2. Working:

The Electromagnetic Induction (EMI)concept is used by WEC. When the magnetic field of the moving magnet cuts the stationary coil, an EMF is generated in the system. Water waves cause vibrations on the exterior body generators. The moveable magnet in the tube, which is connected to the outer body through springs, moves as a consequence of these vibrations. The ferrofluids in the tube assist to reduce motion damping and improve the model's efficiency. A liquid that is drawn to the poles of a magnet is known as ferrofluid. It is a colloidal liquid composed of ferromagnetic particles dispersed in a carrier fluid, most often water. To prevent clumping, each magnetic particle is fully covered with a chemical agent capable of lowering the surface tension of the liquid in which it is dissolved. The basic unit's output is a low-powered AC signal that will be converted to DC.The block diagram of the working of the WEC is shown in Fig. 5.

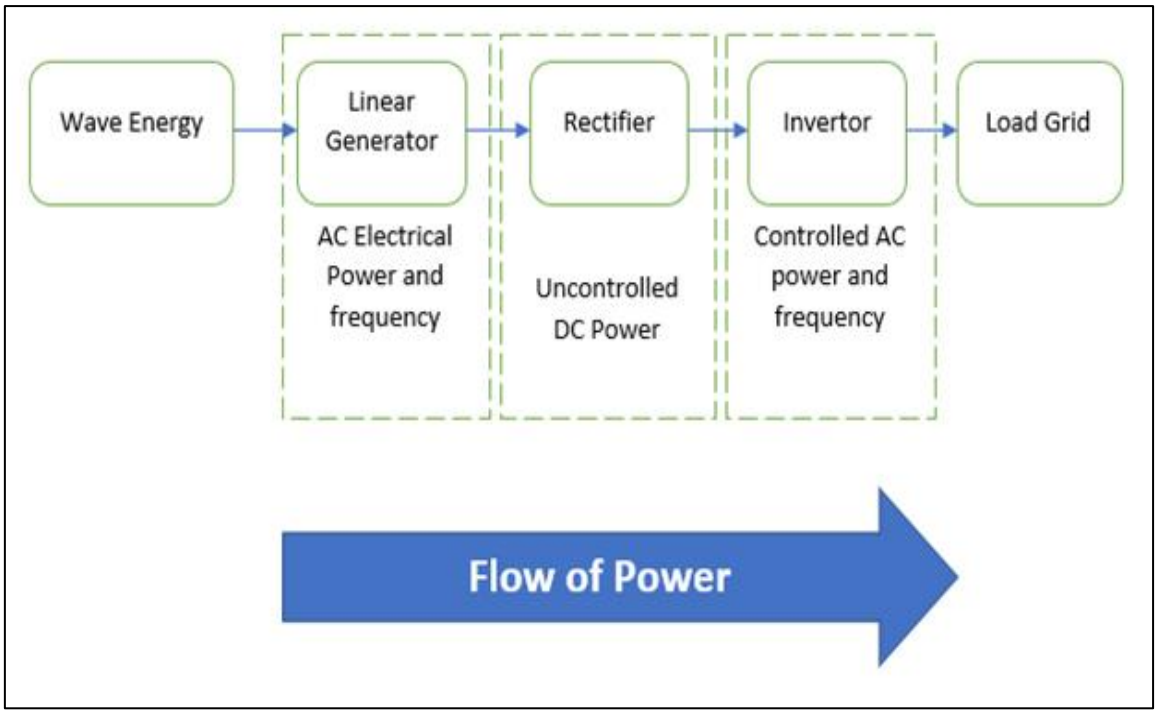

Figure3: Illustrates the block diagram of the power flow of the WEC.

4. DISCUSSION

The kinetic energy of the wave may be converted into electrical energy using this method. Due to the waves in the water, the floating body travels up and down, and the connected spring causes the magnet to move. A magnetic field crosses the coil as the moveable magnet passes across it, inducing an EMF and generating a current in the coil. Figure 4 shows the PMLG's output power for various wave qualities. The measured output power at various wave height and wave period values is displayed in this diagram. The output power rises as the wave height or period increases, according to the results.

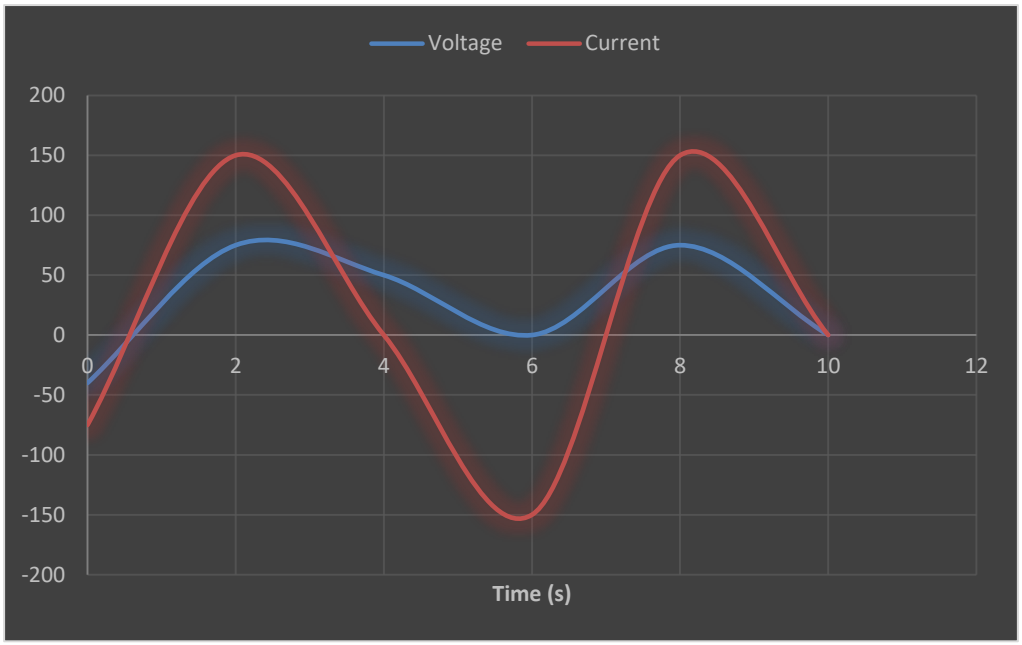

Figure 4: Illustrate the waveform of the output phase voltage and phase current of the floating wave energy conversion device[2]**.**

This WEC allows for the direct conversion of mechanical energy to electrical energy. Figure 4 shows a variable frequency and amplitude waveform that must be rectified before being converted into a sinusoidal fixed voltage and frequency waveform utilizing power electronics for grid connection. Passive or active correction is possible. A simple diode bridge may be used as a passive rectifier, and this has a power factor of one.

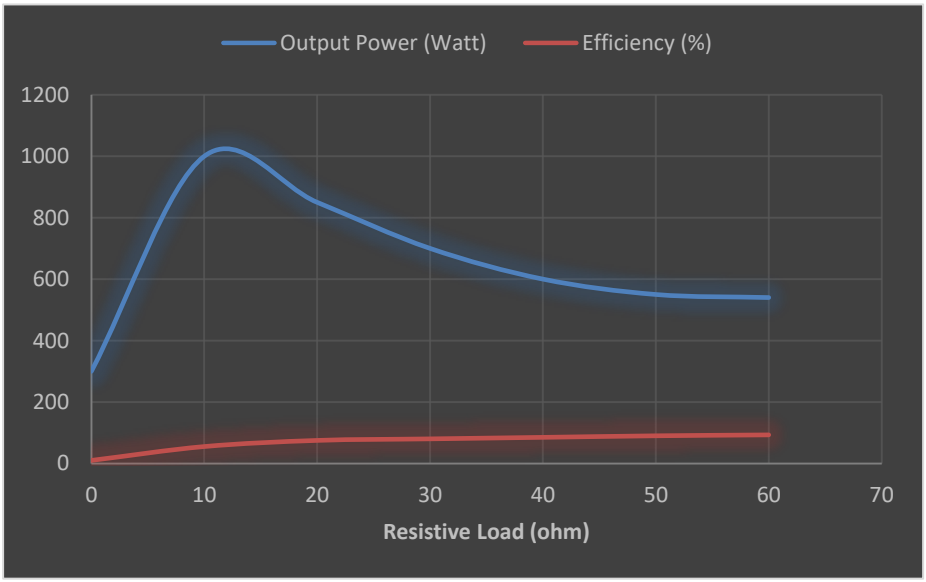

Figure 5: Illustrates the output power and the efficiency of PMLG on different resistive loads[2]**.**

Figure 5 depicts the PMLG's characteristics under various external load resistances. It can be observed that when the resistance rises, the output power increases first. When the load resistance reaches a particular level, the output power begins to drop. The PMLG's efficiency, on the other hand, improves as the load rises. The gradient of the increase, however, begins to diminish at a certain point, and the efficiency begins to stabilize.Wave energy may be extracted

using a number of techniques. Different devices and systems collect wave energy using different ways and convert it to electricity using different methods. Wave energy converters are categorized based on where they're used, how they get their power, and what kind of wave energy conversion technology they use. WECs may be divided into three categories depending on where they are placed in the ocean: shoreline, nearshore, and offshore. Shoreline WECs are placed along the water's edge. They offer the benefits of being simple to install and maintain, as well as not requiring anchoring or lengthy lengths of underwater electrical lines. Shoreline devices, on the other hand, would not be subjected to as strong waves as those found nearshore and offshore. The transitional zone between deep and shallow water may be described as the nearshore area. Nearshore WECs provide comparable benefits to shoreline WECs, although they are subjected to greater wave force. Offshore WECs are subjected to stronger waves than those found in deep water. The WEC must be placed in regions with high wave energy density that are not shielded.The discussed WEC has the advantage of being able to be placed in any part of the ocean, including the coastline, near shore, and offshore. To offset the drawback of a weaker wave if the WEC is placed near the coast, ferrofluids are employed, which decrease the damping of the moveable magnet's motion and improve the WEC's efficiency. Because of its easy power take-off system, it may also be placed offshore.

5. CONCLUSION

As previously stated, a variety of power take-off methods have been suggested for use in WEC, and several have already been successfully tested. It is unclear, given the present level of technology, which of the many technologies will win the race. Electrical linear generators have a lot of good qualities; however they have a lot of weight and thus a lot of expenses. Alternatives such as dielectric elastomer generators may also prove to be viable candidate systems. Mechanical transmission systems can be the same way. However, further study is needed to understand the features of these technologies in terms of WEC application and to solve the current limitations.For the time being, WEC with floating type PMLG seems to be the best option for converting wave mechanical energy to electrical energy. The WEC uses permanent magnets and ferrofluids to capture ocean power or the hydrokinetic potential of waves. The device converts the hydrokinetic potential of waves in the ocean or any large body of water using multiple PMLG cascaded in series and parallel configurations, but it can also be used on any surface that produces perpetual oscillatory/vibratory motion to produce an electric current that can then be converted to alternating current or direct current depending on the application. Despite the fact that previous study in this area has been conducted, there is a significant need for additional research in this field in the future.

ABSTRACT

In recent years, a rising expectation has been built around the analysis of huge quantities of data often accessible in companies, which has been examined by academics and effectively utilized by business. Big Data and Deep Learning are two of the most often used phrases in scientific circles nowadays. In this two-part study, we want to shed some light on the present status of these two distinct but connected areas of Data Science in order to better understand the current state and future development of healthcare. We begin by providing a basic review of the technical components of Big Data technologies, as well as an overview of the elements of Deep Learning methods as described in scientific literature. Then we focus on the application areas that may be claimed to have produced meaningful real-world success stories, with examples ranging from major technology firms to financial institutions, among others. The academic effort that has gone into bringing these technologies to the healthcare sector is then summarized and analyzed in two ways: first, the landscape of application examples is globally scrutinized according to the varying nature of medical data, including data forms in electronic health records, medical time signals, and medical images; and second, a specific application example is scrutinized according to the varying nature of medical data. The freely accessible MIMIC dataset includes a collection of toy application examples designed to assist novices get started with some principled, simple, and structured content and code. Current and future obstacles to the employment of both sets of methods in our future healthcare are discussed critically.

1. INTRODUCTION

Health care is entering a new age in which rich biological data is becoming more essential. Precision medicine, for example, aims to ‘ensure that the correct therapy is given to the right patient at the right time' by taking into account a variety of factors in a patient's data, such as molecular trait variability, environment, electronic health records (EHRs), and lifestyle.The

abundance of biological data presents both possibilities and difficulties for health-care research. Exploring the relationships between all of the various bits of information in these data sets, in particular, is a critical issue for developing effective medical tools using data-driven methods and machine learning. Previous research attempted to connect various data sources in order to create collaborative knowledge bases that could be utilized for predictive analysis and discovery. Predictive tools based on machine learning methods have not been extensively used in medicine, despite the fact that current models show tremendous potential. In reality, due to their high dimensionality, variability, temporal dependence, sparsity, and irregularity, making full use of biological data remains a major problem. Various medical ontologies used to generalize data (e.g. Systematized Nomenclature of Medicine-Clinical Terms, Unified Medical Language System (UMLS), International Classification of Disease-9th version (ICD-9), which frequently contain conflicts and inconsistency, exacerbate these challenges.

Across the data, the same clinical trait may be represented in a variety of ways. For instance, in EHRs, a patient diagnosed with ‘type 2 diabetes mellitus' may be recognized by laboratory results of hemoglobin A1C >7.0, the existence of the 250.00 ICD-9 code, and the mention of ‘type 2 diabetes mellitus' in free-text clinical notes, among other things. As a result, harmonizing all of these medical ideas in order to create a higher-level semantic framework and comprehend their relationships is difficult. In biomedical research, having a domain expert define the phenotypes to employ on an ad hoc basis is a typical method. The supervised specification of the feature space, on the other hand, scales poorly and loses out on new pattern discovery possibilities. Represent learning techniques, on the other hand, enable for the automated discovery of the representations required for prediction from raw data. Deep learning methods are representation-learning algorithms with multiple levels of representation. They are created by composing simple but nonlinear modules that each transform the representation at one level (starting with the raw input) into a representation at a higher, slightly more abstract level. In computer vision, voice recognition, and natural language processing applications, deep learning models performed well and showed significant promise.

Deep learning paradigms offer intriguing new possibilities for biomedical informatics, given their proven effectiveness in many areas and the fast development of methodological advances. Deep learning techniques are either being used or are being considered for use in health care. Enlitic is employing deep learningintelligence to detect health issues on X-rays and Computed Tomography (CT) scans while Google DeepMind has revealed intentions to apply its skills to health care. Deep learning methods, on the other hand, haven't been well tested for a wide variety of medical issues that might benefit from its capabilities. Many features of deep learning, such as its better performance, end-to-end learning scheme with integrated feature learning, and capacity to handle complicated and multi-modality data, may be beneficial in health care. To speed up these efforts, the deep learning research community as a whole must address several challenges related to the characteristics of health care data (i.e. sparse, noisy, heterogeneous, time-dependent), as well as the need for improved methods and tools that allow deep learning to interface with health care information workflows and clinical decision support. We explore current and upcoming applications of deep learning in medicine in this article, emphasizing the main elements that will have a major effect on health care[1]. We do not want to give a detailed background on technological specifics or generic deep learning applications. Instead, we concentrate only on biological data, including that derived from clinical imaging, EHRs, genomics, and wearable devices[2]. While new types of data, such as the metabolome, antibodyome, and other omics data, are anticipated to be useful for health monitoring, deep learning has not been utilized much in these areas to yet.

As a result, we will quickly explain the basic deep learning framework, examine some of its medical applications, and explore the possibilities, difficulties, and uses of these techniques in

the context of precision medicine and next-generation health care in the following sections.When neural networks began beating competing techniques on many high-profile image analysis benchmarks, deep learning came to prominence in computer vision. Most notably, a deep learning model (a convolutional neural network) halved the second best error rate on the picture classification challenge on the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) in 2012[3]. Until recently, enabling computers to identify things in natural pictures was considered to be a tough job, but convolutional neural networks have now exceeded even human performance on the ILSVRC, and have effectively completed the ILSVRC classification test. For a broad range of computer vision issues, deep learning methods have become the de facto norm. They are outperforming other approaches in areas like natural language processing speech recognition and synthesis and the analysis of unstructured, tabular-type data using entity embeddingsand in the analysis of unstructured, tabular-type data using entity embeddings.Deep learning's rapid advancement and broad reach, as well as the consequent spike in attention and multibillion-dollar investment, have sparked a virtuous cycle of advancements and investments throughout the whole field of machine learning. It is currently one of the most popular fields of study worldwide and machine learning experts are in great demand in both business and academia.

1.1 History Of Deep Learning In Health Care

Deep learning has already had an impact on the healthcare field. Google has invested a lot of effort looking at how deep learning models may be used to make predictions about hospitalized patients, assisting doctors with patient data and outcomes management. The blog article, titled "Deep Learning for Electronic Health Records," went on to explain how deep learning might be utilized to decrease administrative burden while improving insights into patient care and needs. This is the greatest use of deep learning in healthcare since it reduces administrative overhead while enabling medical practitioners to concentrate on what they do best: health[4]. The NHS in the United Kingdom has made a commitment to using deep learning, AI, and machine learning to become a leader in healthcare. This technology's worth has been acknowledged by the healthcare provider. The potential to improve patient care via the use of intelligence analytics and deep learning toolkits is certainly appealing to the NHS, which is beset by cost reduction, Brexit, and continuing talent shortages[5]. Investing in deep learning technologies may help the company avoid some of the historical issues that have hampered efficiency while also simplifying patient care. It may also offer much-needed assistance to healthcare practitioners. Boris Johnson pledged £250 million to deep learning in healthcare projects for the NHS in August 2019, reaffirming the fact that AI, machine learning, and deep learning will be a part of the government institution's future. While there are some concerns about AI's possible use in the NHS, a recent study published by the Lancet Digital Health Journal added to its legitimacy[6]. The performance of deep learning models was found to be comparable to that of health-care experts, according to the study.A surprising statement that came with several qualifiers but ultimately highlighted how deep learning in healthcare might help patients and health systems in real practice[7]. Medical imaging solutions, chatbots that can identify patterns in patient symptoms, deep learning algorithms that can identify specific types of cancer, and imaging solutions that use deep learning to identify rare diseases or specific types of pathology are all examples of deep learning applications in healthcare. Deep learning has proven helpful in giving medical personnel with insights that enable them to detect problems early on, allowing them to provide much more customized and relevant patient care[4].

1.2 Future Of Deep Learning In Health Care

There has never been a more exciting time in the history of healthcare. Deep learning in healthcare may become extremely effective for assisting doctors and changing patient care, not just because AI and ML provide the potential to create solutions that respond to highly particular

business requirements. Dr. Eric Topol, a cardiologist and geneticist, has released a book titled 'Deep Medicine,' in which he discusses how deep learning in healthcare may 'restore the caring in healthcare.' He eloquently explains why deep learning is so important to the healthcare industry in his interview with The Guardian. Aidoc, for example, is built on this same concept. It's not meant to take the place of a doctor, but rather to complement him or her. In the end, deep learning will not be able to replace humans, but it will provide doctors the tools they need to succeed in their chosen field. Within the radiology field, for example, Aidoc has created algorithms to speed up patient diagnosis and treatment. The Food and Drug Administration, the European Union CE, and the Therapeutic Goods Administration of Australia (TGA) have all given the business certification and clearance for its specialized algorithms. Intracranial bleeding, pulmonary embolism, and cervical-spine fracture are among the algorithms that enable the system to prioritize which individuals need medical attention the most. This specific use of AI and deep learning aids the overworked radiologist by highlighting things of concern, allowing the healthcare professional to guide patients with more control and efficiency. It also cuts down on paperwork by connecting with processes and increasing access to pertinent patient data. Is deep learning the future of healthcare as a result of all this

Yes, it's possible. Finally, medical technology is becoming more capable of incorporating AI-based algorithms that may expedite and simplify complicated data processing while also improving diagnosis[8]. It has the ability to learn and be trained. It may enhance processes and minimize reporting delays[4]. In a time and money-strapped environment, it may also be utilized to alter the standards for patient care. Deep learning will continue to gain traction in the healthcare sector, particularly now that more medical professionals are seeing its benefits. Only close cooperation with industry and specialized groups can benefit this technology. To guarantee that it is constantly relevant to the profession, it must stay flexible and adaptable. Aidoc's deep learning radiology solution has already seen many successful deployments, increasing clinician assistance and optimizing productivity. Radiologist duties are more efficiently balanced, and abnormalities are promptly recognized and prioritized. Radiologists work 10- to 12-hour days to keep up with severe workloads and industry standards, making it one of the most stressful professions[9]. They may spend more time dealing with patients and other professionals while still receiving detailed analysis of medical images and data thanks to Aidoc.While deep learning's promise in healthcare is barely being realized, it has already yielded substantial benefits. Leading organizations and medical authorities have acknowledged the advantages it provides, and the solutions' popularity has skyrocketed. AI and deep learning in healthcare applications now have their own floor, exhibit space, and talks at the RSNA conference, while they had just one or two booths in 2017. The future is still in the hands of medical experts, but they are now aided by technology that recognizes their specific requirements and surroundings and helps them cope with the everyday pressures they face[10].

1.3 Application Of Deep Learning In Health Care

For a long time, AI, machine learning, and deep learning have gotten a lot of press. Retail, banking, travel, manufacturing, healthcare, and other sectors are all being transformed by this technology. The healthcare sector is one of the industries that uses this technology the most. Because health is so important, medical professionals are always looking for innovative methods to integrate new technology and provide meaningful outcomes. In healthcare, deep learning has game-changing applications. Deep learning collects a large amount of data, such as patient records, medical reports, and insurance information, and uses neural networks to provide the best results.Medical practitioners and academics are using deep learning to uncover hidden possibilities in data and better serve the healthcare sector. Deep learning in healthcare enables physicians to correctly analyze any illness and effectively treat it, resulting in improved medical choices.

- Drug development:Deep learning in healthcare aids in the discovery and development of new medications. The technology examines the patient's medical history and recommends the most appropriate therapy. Furthermore, this technology extracts information from patient symptoms and testing.
- Imaging in medicine:Heart disease, cancer, and brain tumors are diagnosed using medical imaging methods such as MRI scans, CT scans, and ECG. As a result, deep learning assists physicians in better analyzing diseases and providing the best therapy to patients.
- Insurance swindle:Medical insurance fraud claims are analyzed using deep learning. It can anticipate fraud claims that are likely to occur in the future using predictive analytics. Deep learning also aids the insurance sector in sending discounts and offers to its target patients.
- Alzheimer's disease:Alzheimer's disease is one of the major problems facing the medical profession. Alzheimer's disease is detected early using a deep learning method.
- Genome: Deep learning is used to comprehend a genome and assist patients in gaining an understanding of diseases that may impact them. In genetics and the insurance business, deep learning has a bright future. According to Entilic, deep learning techniques are used to make physicians quicker and more precise. Cellscope employs deep learning techniques to enable parents to monitor their children's health in real time through a smart gadget, reducing the need for frequent medical visits. Deep learning in healthcare can provide amazing applications for doctors and patients, allowing doctors to make better medical decisions.

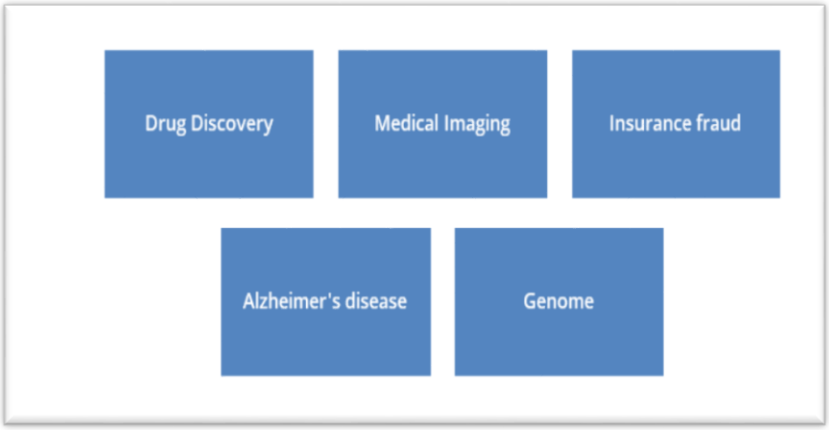

Figure 1: Diagrammatic Representation of Application of Deep Learning in healthcare [ALLERIN]

2. DISCUSSION

Despite the fact that deep learning is still in its early stages, published research have demonstrated that it is capable of making quicker and more accurate diagnoses in physiological data. That potency may prompt a move away from commonly used decision support techniques like Support Vector Machine (SVM) and K-Nearest Neighbor (K-NN) in favor of deep learning. that using deep learning to analyze ECG data resulted in promising diagnostic results. This is due to the created model's ability to capture the unique characteristics of ECG data. As a result, even without large data, the network may be trained using these learnt characteristics, resulting in acceptable diagnostic performance. The automatic analysis of EMG and EEG data, on the other hand, is more difficult due to their chaotic character. As a result, learning from the hidden and nuanced information contained in these signals is more difficult for the network.During the content evaluation, we looked at the many kinds of DL algorithms they utilized in their study. The number of research that utilized a specific DL method to evaluate physiological data is

shown in Table 6. CNN was utilized in five, fifteen, ten, and two studies on EMG, EEG, and ECG, respectively. CNN was used 32 times in total, making it by far the most common deep learning method. LSTM, which was solely utilized for ECG processing, is at the bottom of the table. Deep learning systems' training methods have a significant computational complexity. As a consequence, the run-time complexity is considerable, resulting in a lengthy training time. This will be an issue throughout the design process, since a designer must choose which deep leaning architecture to utilize during this phase. The tuning settings must be changed once the architecture has been selected. The model will be influenced by both structure selection and parameter adjustments. As a result, numerous test runs are required. Shortening the deep leaning model's training period is a hot topic of study. In a parallel distributed processing system, the issue is to speed up the training process. The bottleneck is the network connecting the individual CPUs. Network latency may be reduced using graphics processing units (GPUs).

3. CONCLUSION

Deep learning techniques based on physiological inputs are used to healthcare applications. The investigation was divided into two parts.The bibliometric keyword analysis based on the co-occurrence map was the initial stage. The link between the subjects addressed in the evaluated articles is shown in this stage of the analysis. Four distinct clusters were discovered, one for each physiological signal. This result aided us in structuring the second analysis step, which is concerned with the content of the paper. As a result, the content of the article was determined by extracting information on the particular application area, the deep learning method, system performance, and the kinds of datasets utilized to build the system.The ability of deep learning algorithms to perform effectively on vast and varied datasets has two implications. For starters, the dataset becomes essential to the system's architecture. As a result, we concentrated our efforts throughout our study on this criterion. We discovered that 31 of the evaluated articles used one or more publicly accessible datasets in their scholarly work. As a result, we believe that the value of these publicly accessible public statistics will grow. Another result is that deep learning algorithms will perform well in real-world situations, since clinical practice generates a lot of data with a lot of variety. However, none of the studies that were evaluated were able to demonstrate this in a real-world context. Another important thing to note is that our literature search turned up just 53 articles. The small number of studies suggests that more research is needed. To be more precise, 53 articles do not represent the whole range of physiological signal-based healthcare applications. More sophisticated deep learning algorithms focusing on the early identification of illnesses utilizing physiological signs may be developed in the future.

ABSTRACT

The present rise in energy costs, as well as the current energy supply's limitations The adoption of novel energy production methods, such as hybrids, is encouraged by resources. High-energy-efficiency integrated systems (using fossil fuels and renewable energy sources). Polygene ration systems are a kind of integrated system. Generate electrical, heating, and cooling at a greater level in various circumstances efficiency than a traditional system, as well as a diverse set of technologies. With a variety of setups, the design of these systems may be complex at times. Carried out with the help of solved and optimized mathematical models Minimizing investment and operating expenses is important, but these optimizations are also important. Techniques are commonly used in industrial settings, but very rarely in residential settings. Applications in buildings or district heating and cooling (DHC). The purpose of this article is to provide a survey of the optimization literature. Methods for developing or DHC apps that have been utilized in the past. TheThe primary goal of this study is to provide the groundwork for the creation of an For the synthesis and design of polygene ration systems, an optimization tool has been developed. its use in efficient district heating and cooling networks their financial investment and operating costs to demonstrate the concept, an example is given This tool's application.

KEYWORDS:*Polygene Ration Systems Optimization, District Heating And Cooling Optimization.*

1. INTRODUCTION

Energy system optimization is a significant problem in the creation of more sustainable development models, particularly in metropolitan settings, where almost all electrical energy is generated in distant large-scale power plants, but cooling and heating needs are met locally in

each residence or structure. In the year 2000, according to the Plan de Acción E4 (a plan for energy savings and efficiency in Spain for the period 2004-2012), 58.4 percent of converted energy was wasted owing to conversion system efficiency and transportation losses. The heavy usage of electrical compression refrigeration units in the summer, as well as electrical heating units in the winter, in temperate areas like Spain, results in intense use of the electrical network, with historical demand peaks in the winter and summer that increase year after year. District Heating and Cooling networks (DHC) and Distributed Energy Systems (DES) are a more dependable and long-term solution. Energy is generated locally, with no energy losses. Furthermore, combining multiple technologies with the usage of renewable energy sources reduces primary energy consumption and pollution emissions. Alanne and Saari go into more depth on the differences between centralized and distributed energy systems [1].

This paper's goal is to look at optimization methods for DHC and DES applications in both residential and industrial settings. The review has been focused and structured according to the main topics involved, due to the lack of previous research on optimization methodologies applied to all the considered technologies integrated in a unique energy supply system (DHC, DES, and renewable energies), due to the lack of previous research on optimization methodologies applied to all the considered technologies integrated in a unique energy supply system (DHC, DES, and renewable energies). Optimization methods, DHC layout, energy supply system design, users' network connection, users' demand modeling, and lastly, the technologies involved in the production energy system The creation of a tool that integrates all of the previously stated subjects will be a future outcome of this study. For heat and power producing systems, optimization algorithms are often employed to identify the optimum alternative configuration or production schedule. Mathematical programming is the most popular technique for DES and DHC, although other approaches like as genetic algorithms, neural networks, and fuzzy logic systems are also often employed. Literature has a broad categorization, review, and short lesson on all of these methods.

Optimization based on several criteria In most optimization issues, there are many conflicting and non-comparable criteria. Economic factors are the most frequent, but additional criteria such as pollutants emissions (environmental criteria), product quality, safety, and flexibility must also be considered. Multicriteria algorithms may be used to compare various power plant types, for example [2] .Calculation of energy demand and load The most essential data for the modeling and optimization process is energy demand. The kind and frequency of the available energy demand data may influence the optimization method used. Simulation tools like TRNSYS or Energy Plus are the most popular method to determine load demand for individual buildings. In other instances, simulation models for calculating energy demand are created using geographical data, consumer type, historical consumption data, and other regional factors. Other models employ recent load data and neural networks to improve load estimation, identify deviations from the expected trend, and correct energy demand predictions, because building simulation programs cannot accurately account for all possible user behaviors affecting the building's energy demand. Regional planning and DHC optimization There are few examples of models that optimize both manufacturing locations and the district network in the literature. Söderman and Pettersson provide an example of a MILP issue that yields the DES structure and the optimum user connection via the primary DH previously established route. There are several commercial DHC simulation programs available, such as TERMIS and WinDes.

TIMES is a mathematical model (MILP implemented in GAMS) that may be utilized on a local, regional, national, or global scale for regional planning. A source of renewable energyBy far the most integrated renewable energy source in urban electricity supply networks is solar energy is an example of their integration in a DHC network. Due to their greater efficiency than direct biomass combustion, biomass gasification for electrical and thermal energy generation is presently garnering a lot of attention[3].In many instances, a single company owns huge

combined heat and power district heating systems. This was common in the former Eastern Bloc nations. However, in many designs, the cogeneration facility is owned separately from the heat-using portion. Warsaw, for example, has a split ownership structure, with PGNiG Termika owning the cogeneration unit, Veolia owning 85% of the heat distribution, and the municipality and employees owning the remaining heat distribution. Similarly, all of Denmark's major CHP/CHP systems are shared ownership. Sweden offers an alternate example of a deregulated heating industry. The ownership of the district heating network is often not separated from the ownership of cogeneration plants, district cooling networks, or centralized heat pumps in Sweden. There are other instances of parallel networks and linked networks where different utilities collaborate as a result of the rivalry. There have been concerns in the United Kingdom that district heating firms have too much of a monopoly and are not adequately regulated, a problem that the industry is aware of and is working to address via the use of customer charters established by the Heat Trust. Some consumers are suing the provider for misrepresentation and unfair trading; alleging that district heating does not achieve the savings that many heat suppliers advertise.

Every district heating system is different because circumstances vary from city to city. Furthermore, since countries have varied access to main energy carriers, they have various approaches to dealing with heating markets inside their boundaries. Euroheat & Power has pushed district heating throughout Europe since 1954. Within their Ecoheatcool project, which is funded by the European Commission, they produced a study of European district heating and cooling markets. According to a second research dubbed Heat Roadmap Europe, district heating has the potential to lower energy prices in the European Union between now and 2050. [49] The EU's CHP Directive is presently influencing the legislative framework in member states of the European Union.Through the CHP Directive, the EU has aggressively integrated cogeneration into its energy strategy. "Security of supply truly begins with energy efficiency," Energy Commissioner Andris Puebla's said during a meeting of the European Parliament's Urban Lodgment Intergroup in September 2008. The Cogeneration Directive 2004/08/EC of the European Union recognizes energy efficiency and cogeneration in the first paragraphs. This directive aims to promote cogeneration and create a system for measuring each country's cogeneration capabilities. The evolution of cogeneration has been uneven throughout the years, and national conditions have dominated the past several decades. The European Union as a whole now produces 11% of its energy via cogeneration, saving Europe an estimated 35 Mtoe per year. However, there are significant variations across member states, with energy savings ranging from 2% to 60%.

Denmark, the Netherlands, and Finland are the three nations in Europe with the world's most extensive cogeneration economy. Other European nations are working hard to improve their efficiency as well. According to Germany, cogeneration may provide more than half of the country's entire energy consumption. Germany has set a goal of doubling its energy cogeneration from 12.5 percent to 25 percent by 2020, and has approved legislation to achieve this goal at the "Federal Ministry of Economics and Technology," (BMWi), Germany, August 2007. The United Kingdom is likewise a strong supporter of district heating. The government established a goal to obtain at least 15% of government energy from CHP by 2010 in order to meet the UK's objective of reducing carbon dioxide emissions by 80% by 2050. Financial incentives, grant assistance, a stronger regulatory framework, and government leadership and collaboration are among the other UK initiatives to promote CHP development. According to the IEA's 2008 cogeneration expansion modeling for the G8 nations, expanding cogeneration in France, Germany, Italy, and the United Kingdom alone would virtually quadruple current primary fuel savings by 2030. Savings in Europe would rise from 155 TWh now to 465 TWh in 2030. From 2030, each country's total cogenerated energy would have increased by 16 percent to 29 percent. Organizations like COGEN Europe, which serves as an information center for the most current

changes in Europe's energy legislation, help governments in their CHP efforts. COGEN is Europe's umbrella group, representing the cogeneration industry's interests, users of the technology, and promoting its advantages in the EU and beyond. Gas and electricity companies, ESCOs, equipment suppliers, consultancies, national promotion organizations, banking and other service businesses are among the members of the association. The Power Plant for District Heating Steyr is a sustainable combined heat and power plant that generates electricity from wood chips. Vienna (Firmware Wien) is Austria's biggest district heating system, with numerous smaller systems scattered throughout the nation.

Wien Energie is in charge of district heating in Vienna. A total of 5.163 GWh was sold in the 2004/2005 business year, with 1.602 GWh going to 251.224 individual flats and homes and 3.561 GWh going to 5211 large clients. The three major municipal trash incinerators produce 116 GWh of electric power and 1.220 GWh of heat, accounting for 22% of the total. 72 percent of the total is waste heat from municipal power plants and big industrial facilities. The remaining 6% is generated by fossil-fuel-fired peak heating boilers. Since 2006, a biomass-fired power plant has provided heat. In the remainder of Austria, modern district heating facilities are built as biomass or CHP-biomass plants, such as Mödling's biomass district heating or Baden's biomass district heating. The majority of older fossil-fired district heating systems include a district heating accumulator, which allows thermal district heating power to be produced only when electric power prices are high.

2. DISCUSSION

2.1. APPLICATION:

The energy demand and expenses, efficiency curves, technical operational limitations, and the selection of which technologies should be included in the optimization model are the model's input parameters. Sun plant output is estimated using solar irradiation for Barcelona (where the polygene ration facility is situated), orientated south and at a 30o angle. The thermal energy output of the plant for each time period is calculated using the efficiency equation for the chosen collectors and the average number of solar daily light hours.

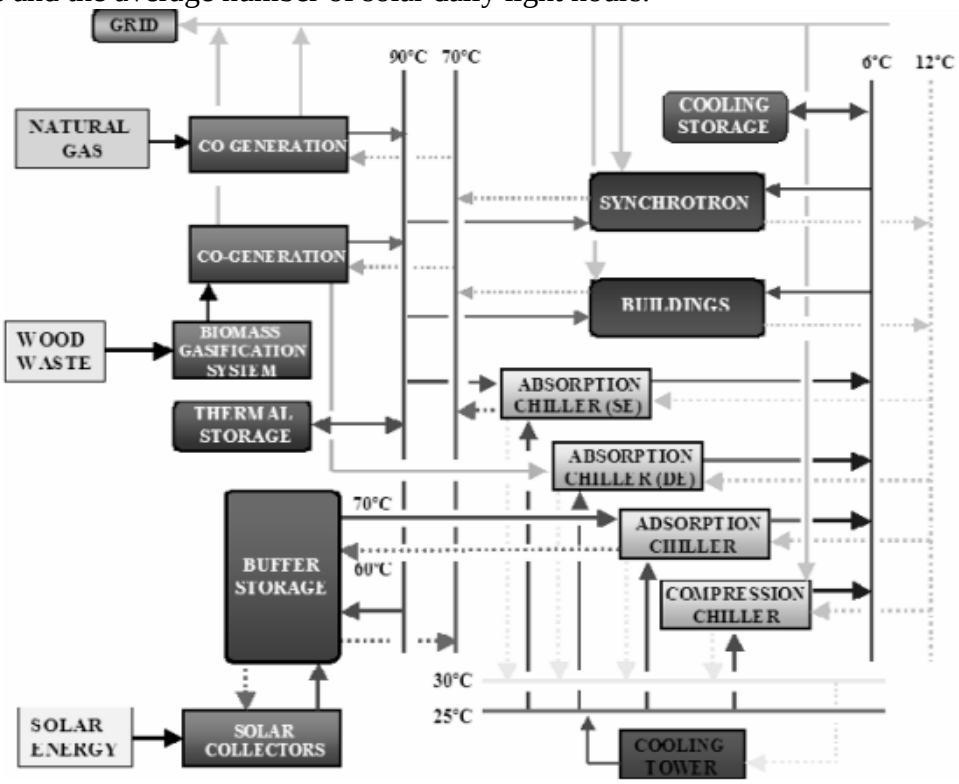

Figure 1. Example of polygene rations system to be optimized using the NLP model.

The energy demand is available for 15-day intervals, dividing the year into 24 parts. The model can be used to compare several alternatives using different technologies, for example, the best solution for a conventional case with boilers and compression chillers can be compared to the best solution for a cogeneration or trigeneration system, and the best solution for the PolyCity project can be compared to the best solution for a conventional case with boilers and compression chillers. Renewable and distributed energy systems, alternatively, result in significant savings in terms of primary energy and CO2 emissions, as demonstrated.Figure1.Example of polygene rations system to be optimized using the NLP model [4].

2.2.ADVANTAGE:

The model's outputs are the technologies used in the final optimum solution, the unit's nominal size, and the operating conditions for scheduling cooling units for the PolyCity system to meet cooling demand. The simple effect absorption chillers supply the base load, while the compression chillers give the peak demand. Adsorption and double effect absorption chillers operate at full capacity nearly all of the time (whenever feasible) to recover all available solar energy and to take advantage of their greater efficiency. The creation of software for the optimization of DES and DHC will be a future application of this study, taking into account all of the factors examined in this review (DES, DHC, user connection, integration of renewable energy technologies, and so on). Another tool in the works will show a 3D scenario of a zone included in the DES and DHC, which may be a single structure, a street, or many districts. This program will be utilized for DHC routing, building energy demand analysis, user connection, and will include DES and renewable energy computation and optimization [5].

2.3.*WORKING*:

District heating (also known as heat networks or teleheating) is a method for distributing heat produced in a centralized place for residential and commercial heating needs such as space heating and water heating via a series of insulated pipes. Heat is often supplied from a cogeneration plant that burns fossil fuels or biomass, although heat-only boiler stations, geothermal heating, heat pumps, and central solar heating, as well as waste heat from nuclear power electricity generation, are also utilized. Compared to localized boilers, district heating facilities may offer greater efficiency and better pollution management. District heating with combined heat and power (CHPDH) is the cheapest way of reducing carbon emissions, according to some studies, and has one of the lowest carbon footprints of all fossil generating facilities. Fifth-generation district heat networks do not utilize combustion on-site and produce zero CO2 and NO2 emissions; instead, they use electricity to transmit heat, which may be produced from renewable energy or from distant fossil-fuelled power plants. The Stockholm multi-energy system employs a mix of CHP and centralized heat pumps. This enables for the creation of heat through electricity when intermittent power production is abundant, and cogeneration of electric power and district heating when intermittent power production is scarce.In general, all contemporary district heating systems are demand driven, which means that the heat provider responds to customer demand and guarantees that the temperature and water pressure are adequate to give the desired heat to the users. The five generations have distinguishing characteristics that distinguish them from previous generations. Each generation's

characteristic may be utilized to determine the state of development of an existing district heating system [6].

The first generation was a coal-fired steam system that was initially developed in the United States in the 1880s and quickly gained popularity in Europe. It was state-of-the-art until the 1930s, and it utilized concrete ducts and worked at very high temperatures, making it inefficient. Due to the heated, pressured steam tubes, there were additional issues with dependability and safety. This generation is now technologically obsolete. Some of these systems, such as those in New York and Paris, are still in operation. Other systems that were constructed in the past have been converted to later generations a new generation The second generation began in the 1930s and continued into the 1970s. It used coal and oil to generate energy, which was then transferred through pressured hot water as a heat carrier. Water pipes in concrete ducts, mainly built on site, and heavy machinery were utilized in the systems, which had supply temperatures exceeding 100 °C. The principal energy savings that resulted from utilizing combined heat and power plants were a major driver for these systems. The soviet-style district heating systems that were constructed after WWII in many nations in Eastern Europe were typical systems of this generation, but they were also utilized in other countries. The third generation was created in the 1970s and has since been utilized in the majority of the following systems all over the globe. Because many of the district heating component manufacturers are located in Scandinavia, this generation is also known as "Scandinavian district heating technology." The third generation employs prefabricated, pre-insulated pipes that are placed directly in the ground and operate at lower temperatures, often below 100 degrees Celsius. After the two oil crises, which resulted in interruption of the oil supply, one of the main motivations for constructing these systems was to improve energy efficiency and ensure supply security. As a result, instead of oil, such systems often utilized coal, biomass, and trash as energy sources. Geothermal and solar energy are also utilized in the energy mix in certain systems. Since the 1970s, Paris has used geothermal heating from a 55–70 °C source 1–2 km under the surface for residential heating. The fourth generation is currently being developed, with the transition to the fourth generation already underway in Denmark[7]. By offering great flexibility to the electrical grid, the fourth generation is intended to fight climate change and incorporate large percentages of variable renewable energy into district heating. The ability to provide existing buildings, energy-renovated existing structures, and new low-energy buildings with low-temperature district heating for space heating and domestic hot water (DHW)."The ability to transfer heat in low-grid-loss networks."The ability to recycle low-temperature heat and incorporate renewable heat sources such as solar and geothermal heat. Ability to be a component of smart energy systems (i.e. integrated smart electricity, gas, fluid, and thermal grids), including 4th Generation District Cooling systems."The ability to guarantee appropriate planning cost, and incentive structures in connection to operations as well as strategic investments linked to the transition to future sustainable energy systems."

Temperature levels have been lowered in comparison to earlier generations to improve the system's energy efficiency, with supply side temperatures of 70 °C and lower. Waste heat from industry, waste-burning CHP plants, biomass power plants, geothermal and solar thermal energy (central solar heating), large-scale heat pumps, waste heat from cooling and data centers, and other sustainable energy sources are all potential heat sources. Fourth-generation district heating

systems are expected to provide flexibility for balancing wind and solar power generation with those energy sources and large-scale thermal energy storage, including seasonal thermal energy storage, for example by using heat pumps to integrate surplus electric power as heat when there is a lot of wind energy or providing electricity from biomass plants when backup power is needed. As a result, large-scale heat pumps are seen as a crucial technology for smart energy systems that use up to 100 percent renewable energy and sophisticated fourth-generation district heating systems [8].

3. CONCLUSION

A number of elements of DES and DHC system optimization have been examined. The most significant disadvantage is the difficulty in determining energy demand, as well as the growing complexity in energy system optimization when a large number of time periods are taken into account. The PolyCity case study was used to create an NLP model for the optimization of a polygeneration plant with a district cooling and heating network, which used fossil (natural gas) and renewable energy (solar and biomass) concurrently with a highly variable energy demand. In comparison to the traditional scenario (electricity purchase, thermal energy generated by boilers, and cooling demand met by compression chillers), primary energy consumption is reduced by 52%, and CO_2 emissions are reduced by 29%. In each time slice examined, the model was utilized to determine the units' optimal size and load.When opposed to individual heating systems, district heating offers a number of benefits. Due to the simultaneous production of heat and electricity in combined heat and power generating facilities, district heating is usually more energy efficient. This also has the advantage of lowering greenhouse gas emissions [9]. In comparison to single boiler systems, the bigger combustion units feature a more sophisticated flue gas cleaning system. District heating systems do not require extra fuel since they collect heat that would otherwise be distributed to the environment in the event of excess heat from industry. District heating necessitates a long-term financial commitment that clashes with short-term investment rewards. Community benefits include decreased investment in individual home or building heating equipment and saved energy expenditures via the utilization of excess and discarded heat energy. District heating networks, heat-only boiler stations, and cogeneration facilities all require a significant amount of upfront capital and finance. These will only be lucrative for owners of district heating systems or operators of combined heat and power plants if they are seen as long-term investments. District heating is less appealing in low-population regions since the investment per home is much greater. It's also less appealing in regions with a lot of tiny structures, such as detached homes, than in places with a lot of bigger buildings, such as blocks of flats, since each connection to a single-family dwelling is very costly. Individual heating systems, unlike district heating systems, may be fully shut down periodically in response to local heating demand [10].

ETHICS MORALITY AND NATIONAL-SPIRITUAL VALUES

Asamatdinov Ergash*

*Candidate of Philosophical Sciences,
Nukus State Pedagogical Institute,
UZBEKISTAN

ABSTRACT

This article scientifically and philosophically explores the views on the concepts used to demonstrate the universal, socio-ethical, spiritual and cultural significance of certain events in value reality.The views of each nation on the presentation of national values without taking into account its history, spirituality, culture, unique customs and traditions are studied from a scientific and theoretical point of view.

KEYWORDS:*Values, Morality, Spirituality, Culture, Customs, Traditions, Nation, Ethnos, Spiritual Heritage.*

INTRODUCTION

Morality is an integral part of our national values. It is difficult to imagine the national values of any nation without its history, spirituality, culture, unique customs and traditions.

ANALYSIS OF THE LITERATURE ON THE SUBJECT: When we say "value", we must understand the set of natural and social blessings and events that serve the interests and goals of nations, peoples and social groups that are important for man and humanity and are valued and valued by them [1; 198].

Values are a set of people who have prestige, prestige, respect, prestige, relationships, situations, material possessions and spiritual wealth among people in society [2; 20].

Values are diverse in nature. Natural, material, spiritual, socio-political and moral values stand out among them. Nevertheless, the highest of values is man himself, his life, his rights and freedoms, his healthy and prosperous life. The glorification of human dignity is an important factor in the purification and development of our society [3; 333].

RESEARCH METHODOLOGY: Value is an integral part of the spirituality of man and society, a concept used to express the value of events, happenings, processes, situations, qualities, demands and procedures in the universe.

Value is a concept used to show the universal, socio-ethical, spiritual and cultural significance of certain events in reality.

National values are a form of identity associated with ethnicity and characteristics that are important to a nation. There is no nation in the world without its own values. National values are inextricably linked with the history, way of life, spirituality and culture of the nation.

G. Gafurov mentioned the following manifestations of national values dedicated to national traditions: 1) natural values; 2) economic values; 3) socio-political values; 4) moral values; 5) moral values [4; 2]. In particular, our ancestors, along with the study of science, instilled in our children the national-spiritual, moral values that are passed down from generation to generation. This is the highest spiritual value, the jewel of the human soul.

Economic value is a concept that means the consideration of mutual interests between individuals in the process of economic relations, the implementation of such qualities as honesty, purity, tolerance, reliability [5; 241].

Spiritual heritage, cultural riches, ancient historical monuments are cited as the most important factors of life values. The essence and significance of each value is determined on the basis of the ability to know the phenomena of nature, society and the spiritual world, to generalize scientifically, to influence social and spiritual development.

Spirituality and culture, which are the basis of national values, mean the beauty of human behavior, generosity, nobility, fidelity to the promise, imagination, knowledge, wisdom, tolerance, decency, cleanliness and purity of heart, sincerity and kindness.

A polite, knowledgeable, hard-working, faithful child is the greatest wealth not only of a parent, but of the whole society. Indeed, every child is formed in an individual family. So, the family is the foundation of a harmoniously developed generation. Therefore, the moral and legal upbringing of children in the family, especially the formation of justice, duty, patriotism, awakening a sense of love for the motherland is very important.

Raising children in the family in the spirit of devotion to their duty is closely linked with such qualities as responsibility, awareness, conscience. At the same time, the sincere relationship between parents, their close and friendly relations with their children, their understanding of their future dreams and goals, will be the basis for the healthy development of children.

When a person has good manners, habits, and intelligence factors in the process of upbringing, he understands life lessons so well and does good deeds, and conversely, the less educated he is, the less life skills he has, sometimes knowingly or unknowingly commits bad deeds. Uradi [6; 19].

We must never lose sight of the mistakes we make in raising children. In our present life, there are some people who are rude, ignorant, and stupid, addicted, addicted to their parents and cause their children to live unhappily. Is it their parents who are to blame? Their child’s human behavior was caused by their indifference to upbringing.

ANALYSIS AND RESULTS: The main purpose of education is to bring up young people to be happy, dear, respected and selfless people of their time.

Any upbringing, especially counseling, begins in the family. The main purpose of education is to bring up people who love each other. Parents should not forget that today a person who does not pay attention to the upbringing of their children will be left homeless and familyless years later.

Abu Hamid al-Ghazali says the following about parenting: “Know! Raising a child is one of the most important things. The child is entrusted to the father and mother. The child's heart is pure, delicate, simple and a jewel free from any patterns and images. It is formed according to the pattern in which it is placed, it bends in the direction of the bend. If a child learns goodness and grows up in goodness, he will find happiness in this world and in the hereafter.

Types of values are personal, professional, national, regional universal. Typology of cultural values of cultural values. Value is a very important event in people's lives. It is divided into economic, technical, social, political, artistic, scientific, moral values. From a formal point of view, value can be distinguished into positive and negative, specific constant, independent and conditional.

In material terms, value is emotional (i.e., a simple sense organ) —it is the value of life, domestic, technical, satisfaction, and so on; divided into spiritual-scientific, moral, aesthetic, religious and others. It is not difficult to determine that some values (economic, technical, political) acquire a historical character, that is, they change with the change of culture, period; other values are permanent, universal (moral, artistic). The second level is related to the choice of image movements or activities that are of interest to social groups that are close to a particular individual.

The third level is the choice of the highest universal goals, which is manifested in the embodiment of goodness, beauty, truth, justice, order, and other opposing evils, lies, ugliness, disorder, and poverty. Values differ sharply in relation to the national and specific civilization of each society. At all times, in all nations, the highest values are expressed in such criteria as kindness, labor, life, love, happiness. National values are a complex socio-spiritual phenomenon that covers all aspects of the language, culture, history, customs, traditions, material and spiritual wealth, economic, socio-political life of the nation.

Universal values are deep and broad in content and have universal significance. Universal values are in line with the goals and aspirations of all nations, peoples and peoples.

Of course, this blessing is shared by his parents, his teacher, and everyone who brought him up. If a child is neglected, grows up in evil, he will suffer misery and perish. In this case, the burden of guilt falls on those who put it, the parents. “In this regard, Allah warns in Surat at-Tahrim: "O you who believe, protect yourselves and your families from the Fire." [7: 121]

With the emergence of humanity, its language, customs, traditions, religion, culture began to emerge moral qualities that represent goodness. Their content reflects the way of life, culture, spirituality, way of life, thoughts of the people.

National values are inextricably linked with the history, way of life, culture and spirituality of the nation.

National values: are formed in an ethnic space that ensures the natural, historical and social unity of people, manifests itself in a variety of ways, has a unique impact on people's consciousness, lifestyle; It is reflected in human relationships, social activities, and is the spiritual basis for these attitudes, activities, goals, needs and aspirations: their emergence as a specific result in the material, spiritual, economic, political and other spheres. , they can have a special significance as a necessity for people, they can also benefit them; in the process of social development, changes and improvements, colorful aspects are passed down from generation to generation, inherited.

CONCLUSION/ RECOMMENDATIONS

Formation of high spiritual qualities such as moral, religious, legal, belief, honesty, corresponding to different forms of values, material, spiritual, cultural, national, universal, regional, social, political spheres of economic, social consciousness.

GRAMMATICAL CATEGORY IS A UNITY OF GRAMMATICAL FORM AND GRAMMATICAL MEANING

UZBEKISTAN

ABSTRACT

Grammar is a system of rules which governs the production and use of utterances in a given language. Grammar has its fundamental notions. The basic notions dealing with the analysis of the categorical structure of the word: grammatical form, grammatical meaning, grammatical category, paradigm. A grammatical category is a class of units (such as noun and verb) or features (such as number and case) that share a common set of grammatical properties. Also called grammatical feature.R.L. Trask notes that usage of the term category in linguistics "is so varied that no general definition is possible; in practice, a category is simply any class of related grammatical objects which someone wants to consider" (A Dictionary of Grammatical Terms in Linguistics, 1996).

KEYWORDS: *Grammatical Form, Categorical, Linguistics, Countability.*

INTRODUCTION

The term category in some approaches [to language] refers to the classes themselves, e.g., noun, verb, subject, predicate, noun phrase, verb phrase. ... More specifically, it refers to the defining properties of these general units: the categories of the noun, for example, include the number, gender, case, and countability; of the verb, tense, aspect, voice, etc. A distinction is often made between grammatical categories, in this second sense, and grammatical functions (or functional categories), such as subject, object, complement.

Grammatical categories are the building blocks of linguistic structure. They are sometimes called 'lexical categories' since many forms can be specified for their grammatical category in the lexicon. However, we will not use the term lexical category here because the term grammatical category is more widely understood, and the category of a word depends as much on how the word is used in discourse as on its conventionalized (lexical) meaning. «Grammatical categories are grammatical properties of notional parts of speech and they are considered as a unity of notions of grammatical meaning and grammatical form. The grammatical meaning is a general, abstract meaning which embraces classes of words. The grammatical meaning depends on the lexical meaning and is connected with objective reality indirectly, through the lexical meaning. The grammatical meaning is relative, it is revealed in relations of word forms: speak — speaks. The grammatical meaning is obligatory. Grammatical meaning must be expressed if the speaker

wants to be understood. The grammatical meaning must have a grammatical form of expression (inflexions, analytical forms, word-order, etc.). Compare the word forms walks, is writing. Both forms denote process, but only the second form expresses it grammatically. The term, form _ may be used in a wide sense to denote all means of expressing grammatical meanings. It may be also used in a narrow sense to denote means of .expressing a particular grammatical meaning (plural, number, present tense, etc.).

MAIN PART

Grammatical elements are unities of meaning and form, content and expression. In the language system there is no direct correspondence of meaning and form. Two or more units of the plane of content may correspond to one unit of the plane of expression (polysemy; homonymy). Two or more units of the plane of expression may correspond to one unit of the plane of content (synonymy).

It is important to keep in mind that a grammatical category is a linguistic, not a real-world, category and that there is not always a one-to-one correspondence between the two, though they are usually closely related. For example, 'tense' is a linguistic category, while 'time' is a category of the world. While past tense usually expresses past time (as in I saw a movie last night), the past-tense auxiliary in the following expresses future time: I wish you would go. And the present-tense verb of I leaves tomorrow expresses future time.

Words are assigned to grammatical categories in traditional grammar on the basis of their shared semantic, morphological and syntactic properties. The kind of semantic criteria (sometimes called 'notional' criteria) used to categorize words in traditional grammar are illustrated in the much-simplified form below:

- Verbs denote actions (go, destroy, buy, eat etc.)
- Nouns denote entities (car, cat, hill, John etc.)
- Adjectives denote states (ill, happy, rich etc.)
- Adverbs denote manner (badly, slowly, painfully, cynically etc.)
- Prepositions denote location (under, over, outside, in, on etc.)

However, semantically based criteria for identifying categories must be used with care: for example, assassination denotes an action but is a noun, not a verb; illness denotes a state but is a noun, not an adjective and Cambridge denotes a location but is a noun, not a preposition. [1]

Although terminology is not always consistent, a distinction should be made between these grammatical categories (tense, number, etc.) and lexical categories, which are closely synonymous with the traditional parts of speech (noun, verb, adjective, etc.), or more generally syntactic categories. Grammatical categories are also referred to as (grammatical) features.

The name given to a grammatical category (as an uncountable noun) is generally also used (as a countable noun) to denote any of the possible values for that category. For example, the values available in a given language for the category "tense" are called "tenses", the values available for the category "gender" are called "genders", and so on.

Categories may be described and named with regard to the type of meanings that they are used to express. For example, the category oftense is considered to serve to express time of occurrence (as in past, present or future). However, purely grammatical features do not always correspond simply or consistently to elements of meaning, and different authors may take significantly different approaches in their terminology and analysis. For example, the meanings associated with the categories of tense, aspect and mood are often bound in up verb conjugation patterns

that do not have separate grammatical elements corresponding to each of the three categories; see Tense–aspect–mood.

The term "grammatical category" refers to specific properties of a word that can cause that word and/or a related word to change in form for grammatical reasons (ensuring agreement between words). For example, the word "boy" is a noun. Nouns have a grammatical category called "number". The values of number are singular (one) andplural (two or more).

1. The boy is playing.

2. The boys are playing.

In sentence 1, "boy" is in its basic form, giving its "number" the value of singular. There is one boy and the related auxiliary verb "to be" is in the singular form (is).

In sentence 2, the form of "boy" has changed to "boys", giving its "number" the value of plural. There is more than one boy and the related "to be" is in the plural form (are). In the above example, the "number" of "boy" influences the form of boy, and also influences the form of a related word (be). "Number" is a "grammatical category".

Grammatical categories are made up by the unity of identical grammatical meanings that have the same form (e.g. singular::plural). Due to dialectal unity of language and thought, grammatical categories correlate, on the one hand, with the conceptual categories and, on the other hand, with the objective reality.

It follows that we may define grammatical categories as references of the corresponding objective categories. For example, the objective category of time finds its representation in the grammatical category of tense, the objective category of quantity finds its representation in the grammatical category of number. Those grammatical categories that have references in the objective reality are called referential grammatical categories. However, not all of the grammatical categories have references in the objective reality, just a few of them do not correspond to anything in the objective reality. Such categories correlate only with conceptual matters:

They are called significational categories. To this type belong the categories of mood and degree. Speaking about the grammatical category of mood we can say that it has modality as its conceptual correlate. It can be explained by the fact that it does not refer to anything in the objective reality – it expresses the speaker's attitude to what he says.

Grammatical categories connect grammar and semantics. They are central to the syntactic structure of clauses; in logic they are important for the analysis of propositions. Briefly, case has to do with the relations between the verb in a given clause and the nouns; aspect has to do with the type of situation and whether the speaker presents a situation as on-going or completed; tense has to do with events being located in past, present or future time by the speaker; mood has to do with whether the speaker presents an event as a fact, a possibility or a necessity, with whether the speaker witnessed a given event directly or has merely heard about it - in short, with the attitudes and expectations of speakers regarding states of affairs and propositions.

Reference grammars of particular languages devote much space to grammatical categories but little or none to constituent structure. Constituent structure does not cause major problems for the non-native learners of a given language but its systems of case-marking, mood, tense and aspect do. All reference grammars for non-native learners covertly use theories of tense, aspect, etc. and a useful exercise for students of languages and linguistics is to compare a given reference grammar with theoretical work on a given category.

A grammatical category is a set of syntactic features that: express meanings from the same conceptual domain; occur in contrast to each other; are typically expressed in the same fashion[2].

ABSTRACT

This study examines thermal storage medium as well as system design alternatives for solar cooling applications. The study is focused on solar cooling applications with heat inputs ranging from 60 to 250 degrees Celsius. High temperature (4100 1C) high efficiency cooling applications are given special consideration, which have been mainly neglected in previous evaluations. The applicability of sensible and latent heat storage materials for double effect and triple effect chillers has been tabulated. It has been given an overview of system designs for water storage (sensible heat) and phase change material storage (latent heat). The article covers the literature on solar thermal air-conditioning systems from both a material and a plant perspective. This involves assessing different management methods for controlling the thermal storage that assist in the efficient operation of a solar air conditioning system. The numerous modeling methods for sizing the solar thermal store are discussed, emphasizing the significant differences in particular storage size when used in various applications.

KEYWORDS:*Thermal Energy Storage, Control Strategy, Solar Cooling, Solar Air-Conditioning, Optimization.*

1. INTRODUCTION

Solar thermal cooling systems utilize solar thermal collectors to convert incoming solar radiation into heat, which is then used to produce cooling through a thermally activated cooling device such as an absorption or adsorption chiller, desiccant system, or ejector refrigeration system. Solar cooling is gaining popularity, with a rising number of installations across the globe. Solar energy; however, is a finite resource. While solar photovoltaic technology is getting more cost-effective at generating electricity, it cannot deliver “firm” power without the additional expense of battery storage. As a consequence, while planning a solar-powered electrical grid, system designers must include in the entire cost of I energy supply and (ii) diurnal matching with demand, as well as the additional cost of storage. Solar cooling provides an alternate method for both lowering emissions and controlling solar intermittency in hot regions, where air-conditioning is responsible for a significant portion of greenhouse gas emissions and dominates

peak energy demand .Solar thermal cooling technology, in particular, provides a considerably less expensive method of storing energy, resulting in lower total system costs [1].

Low-cost thermal storage may prove to be a major advantage for controlling energy flows in the retail electricity market, just as it is a key reason for concentrating solar output in the wholesale electricity market. In a solar cooling system, the use of thermal storage may improve the percentage of total building energy demand that can be provided by solar. Although there have been review articles on thermal energy storage, they have mostly concentrated on the storage medium and heat exchanger design elements of a solar cooling system. A plethora of information on thermal storage for solar thermal power generating systems is also accessible. However, none of these reviews have adequately documented the integration aspects of a thermal storage system in the design of a solar cooling plant, nor have they covered the system control approaches required for managing the thermal store's charging and discharging in order to maximize cooling output and achieve reliable operation. This study focuses on thermal storage for high efficiency double effect and triple effect absorption chillers, in addition to these thermal storage integration problems. Because high chiller efficiency may possibly allow solar collector area to be decreased, this is a relatively recent field of solar cooling research with the potential to improve the overall economics of solar thermal cooling systems [2]. When opposed to just utilizing solar heat (as is for hot water or space heating) without additional conversion to chilling, White and Goldsworthy emphasize the necessity of high efficiency chillers as the sole method to truly enhance the value of collected solar heat. Thermal storage, on the other hand, becomes more difficult in these systems since water as a thermal storage medium necessitates the employment of costly pressure vessels. The hot thermal storage component separates two flow loops in this basic solar thermal cooling system. Heat is transferred from solar thermal collectors to the thermal storage through a solar heating flow loop. Heat is transferred from the thermal storage to the thermal cooling device through a thermal cooling flow loop. The thermal store is charged when the heat from the collectors exceeds the heat being used by the thermal cooling device. When the demand for heat from the thermal cooling device exceeds the amount of solar heat available, the thermal storage is depleted to meet the need. The thermal store in most solar cooling systems to date (see Section 3) utilizes a sensible heat storage medium that is the same as the liquid heat transfer fluid in one or both flow loops. Direct thermal storage is the simultaneous capture, transmission, and storage of heat. A distinct storage medium from the collector heat transfer fluid is used in an indirect thermal storage system, which incorporates some kind of heat exchange arrangement. The thermal store's operation and performance are clearly intertwined with the process flow arrangement/design of the whole solar cooling system. This is reflected in the thermal store's working temperature, which is determined by the thermal cooling mechanism. Absorption chillers, for example, are classified into three types depending on the temperature of the heat input needed to operate them. When choosing a solar collector and an appropriate storage material for solar cooling systems, the chiller's working temperature is obviously a crucial consideration. As a consequence, the typical solar thermal cooling flow system [3].

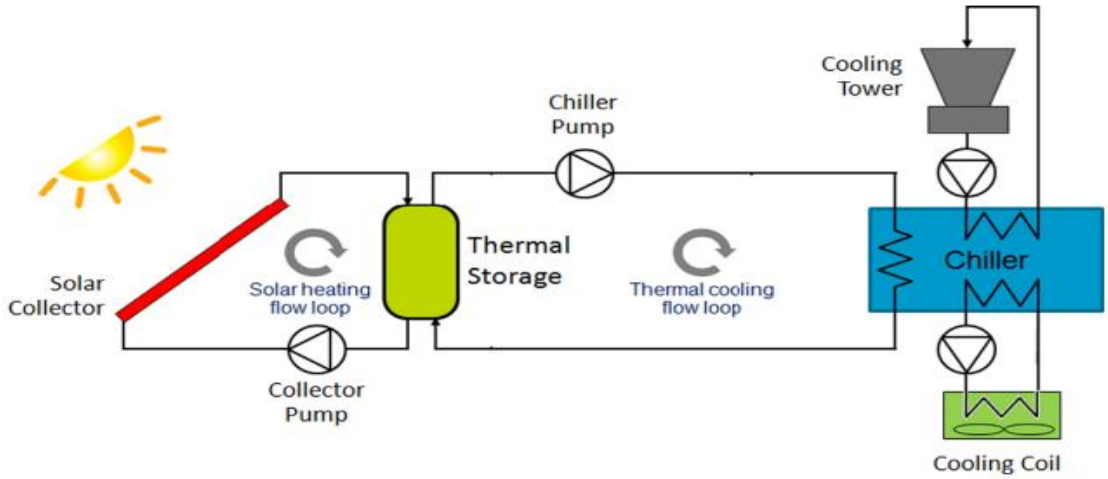

Figure 1: A Generic Solar Thermal Cooling System.

Frost protection, for example, may need an extra flow loop between the thermal storage and the solar thermal collectors placed outside. Alternatively, the possibility of high pressures may make using low volatility heat transfer fluids in a separate atmospheric pressure flow loop appealing. Additional heat exchangers, either external or internal to the thermal storage, are required for additional flow loops. Section 5 goes into heat exchange choices in more depth. A variety of application constraints/alternatives, such as the potential inclusion of potable hot water production and the optional use of gas as a backup heat source, may further affect the architecture. Figure 1 shows A Generic Solar Thermal Cooling System.

2. DISCUSSION

2.1.APPLICATION:

Only a few instances of latent heat storage in solar air-conditioning systems are available. As part of the IEA solar heating and cooling task force, laboratory prototypes for LHTES for solar heating and cooling were examined. They discovered that, in contrast to water, the storage density is significantly influenced by the temperature lift (temperature differential between tank top and bottom) in the storage tank. A laboratory pilot plant has been constructed at the University of Lleida in Spain to evaluate various TESSs and materials for high temperature solar air-conditioning applications with double effect absorption chillers. The facility consists of three parts: a heating system, a storage system, and a cooling system. In lieu of the solar collector and absorption chiller, an electrical boiler (24 kWe) and a dry cooler (20kWe) are utilized to supply heat input and remove heat from the storage system for testing reasons. With a phase change of approximately 170 1C, this facility was utilized to evaluate the performance of hydroquinone and D-mannitol as latent heat storage materials. In contrast to the hydroquinone material, testing revealed that during the heat storage discharge cycle, undesired sub-cooling (below the material freezing point) occurred for D-mannitol. The effect of two alternative thermal storage heat exchange designs based on finned and un-finned shell-and-tube TES was also investigated. A 17.6 kW PCM storage tank was developed and constructed based on these laboratory findings for use in an actual solar cooling facility in Seville, Spain. It was placed on the top of the Engineering School building at the University of Seville as part of a solar refrigeration system. Its primary purpose is to supply heat to the solar cooling system when the sun isn't shining. A cylindrical vessel with a tube bundle within makes up the design. The heat transfer fluid circulates within the tubes, which are arranged in a triangle pattern, and the PCM is housed in the outer tube portion [4].

2.2.ADVANTAGE:

Heat may be stored in the form of sensible heat, latent heat (which requires a phase shift in the storage substance), or reversible physic-chemical processes in the storage medium. While sensible storage dominates current installations, the decrease in space needed for the thermal store is an encouragement for alternative types of thermal energy storage. When storing 10 MJ of heat, shows the impact of storage material choice on the TES system volume. in 46 solar cooling systems. the picture and characteristics of a latent heat thermal energy storage system built in Seville, Spain. The assessment of a variety of additional thermo-physical and chemical characteristics of prospective materials is also required when determining a suitable material for a particular application. This section is an overview of storage material research that may be used for solar cooling. In a sensible heating process, the quantity of energy transferred to the storage media is proportional to the difference between the storage medium's final and starting temperatures, its mass, and its heat capacity. Sensible storage may take the shape of I a solid substance that is heated and cooled indirectly by a heat transfer fluid, or (ii) a liquid material in a storage tank [5].

2.3.WORKING:

Water is the most frequent substance utilized in sensible heat storage systems. Water is a useful storage medium for low temperature sun cooling applications (e.g. single stage absorption chillers and desiccant systems) because of its high specific heat capacity, broad availability, chemical stability, and cheap cost. The use of water as a sensible heat storage medium for high temperature applications. To handle water in a liquid condition, triple effect chillers with a heat input of 200 1C may need a storage tank and pipes built for 35 bar. The application was found to be appropriate for both concrete and castable ceramics materials. Concrete is especially appealing because of its reduced cost, increased strength, and ease of handling. A broad range of materials appropriate for high temperature solar power plants is described in the NREL study, together with the experience of prior thermal energy storage systems used to solar parabolic trough power plants. Salts in molten form are a possible option for sensible heat storage, despite their primary usage in phase transition applications. They are appealing because of their cheap price. Materials having an energy density ratio greater than 0.5 were chosen. Sandstone is the sole exception owing of its strong heat conductivity. The source has no information about the price. Materials with comparable energy densities to water (e.g. asphalt sheet) may be a good option for high-temperature storage (4 100 1C). In conclusion, owing to its thermal characteristics and low cost, water is the most appropriate option for single effect chiller applications. Materials like synthetic oil, concrete, and asphalt may be good candidates for double and triple effect applications.

Thermal storage system design, cooling system needs, and economic limitations would all influence the ultimate decision. Heat associated with phase change is stored in these materials. The amount of heat stored in these materials is related to the mass of the material, the percentage of the material that undergoes phase transition, and the heat of fusion of the substance. Phase change materials are the materials that are utilized to store latent heat (PCM). Solid–solid, solid–liquid, solid–gas, and liquid–gas are all examples of phase transitions. The first example is concerned with storing heat via transitions between various types of crystallization forms, and it is distinguished from the others by a low latent heat and modest volume changes [6]. Solid–liquid and liquid–gas transitions are coupled with large volume changes, resulting in system complexity and containment issues, making them unsuitable for TES applications. Although the latent heat of the solid–liquid phase transition is lower than that of the liquid–gas phase shift, the volume change is less. As a result, they have been extensively researched in recent years. The three types of phase transition materials utilized in latent heat thermal energy storage are organic, inorganic, and eutectic. Paraffins (organics), hydrated salts (inorganic), and fatty acids (inorganic) are the most widely used materials in practical applications. Metal alloys, on the

other hand, may be able to overcome the poor heat conductivity of solid organics and salts. The authors created a two-stage absorption chiller with a thermal energy storage system for a solar cooling facility. The temperature range was the first criterion: the solar cooling system's working temperature for the double effect absorption chiller had to be between 140 and 200 1C, with the latter being the maximum collector output temperature. The heat of fusion was the second choice parameter: As a reference point, a heat of fusion greater than 150 kJ/kg was selected. The authors next conducted a literature study and conducted experimental experiments to evaluate various materials, compiling a This method was used to choose D-mannitol and hydroquinone. Low heat conductivity is a common problem with many phase transition materials, such as sun salt (KNO3/NaNO3). When thermal conductivity is poor, the solid layer produced on the exterior during heat discharge may act as an insulator, preventing heat transmission from the inside molten PCM solidifying. Metal constructions composed of steel or stainless steel that serve as carriers are used. Within the PCM, there is a dispersion of high conductivity material, such as copper, silver, or aluminum particles. Materials with high conductivity and low density, such as carbon fibers and paraffin composites, are used. Metal foam (copper, steel, or aluminum) or porous substance like graphite is impregnated with high conductivity porous materials. The scientists examined several techniques and discovered that the metal foam technique is the most promising and appropriate strategy for increasing the thermal conductivity of a PCM in terms of cost, handling, and availability.

3. CONCLUSION

This paper provided an overview of thermal storage materials, storage systems, control methods, and design strategies that are applicable to solar cooling applications (across a variety of temperature ranges). The following is a summary of the major findings from this literature review. In the literature, there are many instances of operating/demonstration units of single stage absorption chiller based solar cooling systems. Water is used as the storage medium in all of these systems. Water is also used as a storage medium in a few installations of double effect absorption chillers. Thermal oil has also been described as a storage medium for double effect chiller systems. Concrete and asphalt, in addition to water and synthetic oil, are regarded as possible low-cost reasonable storage materials. This page has a long list of possible latent heat storage materials. They've been divided into three categories based on their appropriateness for single, double, and triple effect chillers. Salts have an excellent cost index but poor thermal conductivity values, as can be shown. Hydroquinone and D-mannitol, both of which have been tested in a pilot plant, have been studied as possible phase transition materials for double effect solar cooling systems. Storage materials based on phase change have not been explored for triple effect chillers. Area choices for collectors High collector specific area (m^2/kW chiller capacity) Low collector specific area (m^2/kW chiller capacity) Autonomous at full capacity (no back-up)solar heating and cooling system To control comfort and avoid on/off cycling, there is a large thermal storage. It is not recommended (poor comfort outcome) Single-stage full-capacity low-efficiency thermal chiller with gas backup To enhance solar percentage while reducing gas usage, a large thermal storage is needed. It’s not a good idea (high petrol prices/high greenhouse gas emissions).

Full-capacity, high-efficiency multi-stage thermal chiller with gas backup It is not recommended (less economic) To reduce heat losses and costs, a small thermal storage is used. Thermal chiller with backup vapor compression chiller of full capacity It is not recommended (less economic) Enough thermal storage to reduce on/off cycling systems that are based. As a result, a publicly accessible chemical database was utilized to find possible candidate materials. Due to their melting point, thermal conductivity, and energy density, metals (e.g. Sn) and metal alloys (e.g. Al-Sn) have a lot of potential. Their cost indices, on the other hand, are expected to be orders of magnitude greater than salts. The designs of hot water storage tank-based storage systems have

been examined. Some of these systems allow heat transfer fluid to be used directly in the tank, while others require a heat exchanger between the solar collector and the tank. The methods for improving and maintaining stratification in these tanks have been outlined. When constructing stratification-based storage tanks, the aspect ratio, placement of input and exit pipes, and mass flow rate are all essential factors to consider [7].

When charging and discharging the storage medium, latent heat based indirect storage systems utilize either packed bed storage or shell and tube heat exchangers. Unfortunately, there is little design experience with latent heat stores in solar cooling systems, with the bulk of latent heat system literature focusing on cold storage at low temperatures. Due to the complexity of the system and the fluctuating nature of the primary energy source, controlling the charging and discharging of the thermal storage during the operation of a solar air conditioning plant is difficult [8]. Although separate control of flows in the collector and chiller loops has historically been used to solve the control issue, look-ahead model-based control methods are starting to emerge in the literature. These methods may be implemented using current control theory tools and have the potential to provide more efficient operating schedules over longer periods of time. To size the thermal store for various applications, quasi-steady state mass and energy balance simulation tools (e.g. TRNSYS, INSEL) have been used extensively. Surprisingly, it does not seem that this has resulted in uniform "rules-of-thumb" sizing. According to a thorough study of the literature, this is due to the broad variety of applications being studied as well as variations in optimization goals.

For various application scenarios, a qualitative guide to storage design intent is proposed [9]. Key research gaps in solar air-conditioning thermal storage (issues for future study) identified by this review include: New phase transition materials (at 180 to 250 1C) are being developed to help reduce the size of thermal storage in high-efficiency, high-temperature solar cooling applications. The additional expense (relative to water) of phase change materials would be justified by the possible decrease in pressure vessel costs, code compliance, and thermal losses when compared to more typical low temperature single stage chiller systems. New sophisticated look-ahead controllers that can regulate the charging and discharging of the thermal storage depending on the building's anticipated need and the solar resource's predicted availability. These control techniques may be utilized to enhance sunlight fraction or provide better comfort assurance in self-contained solar thermal air-conditioning systems. The effect of an absorption chiller's thermal mass and dilution cycle on the minimum thermal storage capacity needed to allow the chiller's robust, mostly steady-state operation in solar air-conditioning applications. Solar cooling's ability to balance out power demand with thermal storage is being investigated in electrical system integration studies. Increased storage would be identified as a benefit to the whole energy system (which may not be immediately apparent from basic stand-alone building airconditioning studies). It would also offer insight into how the proportion of solar energy in the electrical system may be raised, eventually leading to a zero-fossil-energy grid [10].

ABSTRACT

Ground penetrating radar is a geophysical instrument that works on the theory of electromagnetic radiation. This method uses a radar pulse to image the Earth's subsurface. GPR is made up of three parts, one of which is the antenna, which houses both the transmitter and the receiver. When a radar signal penetrates into the ground and returns a revert signal after reaching an item, information about the utilities existing under the ground is given. High gain and broad bandwidth are two antenna characteristics that may be considered for deep penetration in GPR applications. The application utilized in this project is a geographic survey of the ground where we may locate utility pipelines such as electricity and water.This paper discusses about the twenty-first century, people may explore the deep ocean using underwater technology such as sonar, scuba diving, and other techniques, but mankind still has no clue what lurks beneath the earth's surface. To learn particular facts, one must either dig the soil or utilize the mining technique.

KEYWORDS:*GPR (Ground Penetrating Radar), GSSI (Geophysical Survey System, Inc.), SIR (System Incorporated Terasirch).*

1. INTRODUCTION

Deepocean exploration is also possible for humans utilizing underwater technology such as sonar, scuba diving, and other methods in the twenty-first century, although humanity still have no idea what lies under the earth's surface. To learn specific data, one must either excavate the soil or use the mining method to identify the soil information. Using electromagnetic radiation, we can penetrate the data up to 15 mm. Ground penetrating radar is one of the electromagnetic radiation-based techniques for studying the earth's knowledge. GPR techniques were originally developed for oil and gas exploration, but they are now being used in a variety of fields, including archaeology, environmental research, geotechnical and hydrological investigations, and so on [1].

Geotechnical is one of the applications that subterranean utilities can readily recognize. The antenna receives an electromagnetic pulse from the radar transmitting under the ground and the return signal since it employs an electromagnetic radiation technique. As a result, we can record the two-way travel time and amplitude of the signal [2]. The signal intensity is what determines the amplitude. The antenna is available in a variety of frequencies, depending on the application. Before constructing houses, malls, or structures, we may obtain a good philosophy of t by doing a GPR survey of the site. This technique provides us with information on underground utilities such as water pipelines, electric lines, sewage lines, metal pipelines, and gas lines, among other things. We can obtain a general notion of any piece of land using this surveying technique [3].

1.1 Ground penetrating radar (GPR);

GPR works by sending electromagnetic waves (in the range of 10 to 10 000 Hz) into the investigated material and receiving the reflected pulses when they pass through discontinuities. A discontinuity may be a border or interface between dielectrically dissimilar materials, or a subsurface item like a deboned or delamination. The type and position of the discontinuity may then be determined using the amplitudes of the received echoes and their associated arrival timings [4].

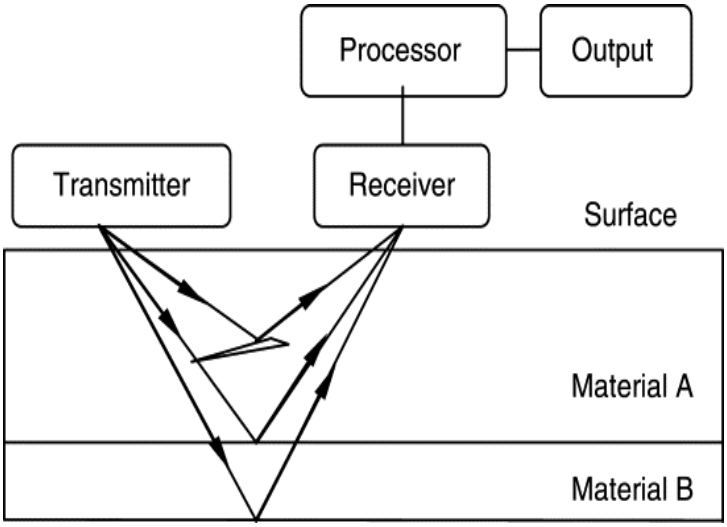

Fig 1: Principle of Testing With GPR System [5]**.**

GPR may now be utilized for subsurface condition evaluation in materials with thin layers, such as FRP composites, thanks to advancements in GPR technology, particularly the increased frequency of commercially available GPR antennas and improved data processing software. GPR waveform analysis may possibly aid in the detection of subsurface debones between the worn surface and the underlying FRP bridge deck, as well as delamination's inside the FRP deck's flanges.

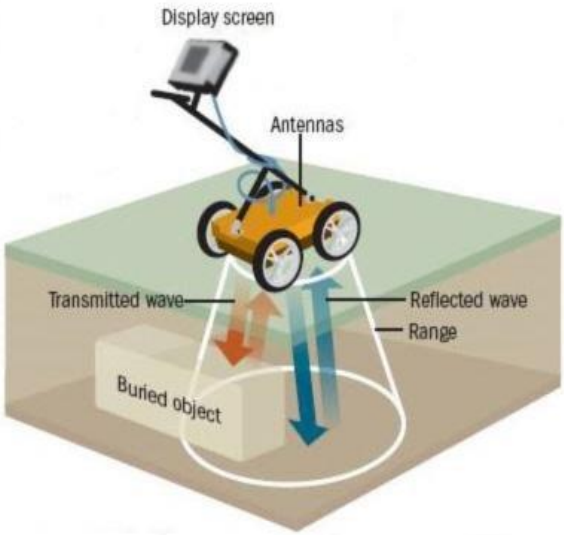

Fig 2: Penetration Radar [6]**.**

GPR has higher penetrating power than other non-destructive methods like infrared thermography, ultrasonic, or microwave, and can identify concrete flaws or deteriorations at larger depths. According to the findings of the literature study, a lower frequency GPR antenna (1 GHz) is unable to identify superficial flaws like deboning in FRP wrapped members, while a higher frequency antenna (2 GHz) can. A ground linked 1.5 GHz antenna, on the other hand, was found to have a greater penetration capacity, which is important for evaluating FRP bridge decking[7]. GPR is an effective technique for identifying water-filled debonings, however its efficacy in detecting air-filled deboning's in FRP wrapped concrete cylinders and FRP bridge decks (Dutta, 2006) is lacking. GPR (Ground Penetrating Radar) is a real-time NDT method that utilizes high-frequency radio waves to provide high-resolution data in a short period of time. This method employs electromagnetic waves that move at a particular speed defined by the material's permittivity [8].

Due to differences in electrical characteristics, velocities will vary depending on the kind of material and therefore produce responses at various times. A series of traces are gathered at specified locations along the survey line as antennas travel along it. The scans are then stacked on top of each other to create a profile of the region. A waveform generator, a single transducer with an emitting and receiving antenna, a signal processor, and a data storage/display device are the primary components of the GPR. For structural applications, several methods have been employed, including frequency modulation, synthetic pulse-radar, and pulse systems [6]. A full-scale railway track with sub-ballast, ballast, wood ties, and rails was built at the University of Massachusetts – Amherst to test the effects of fouling percentage, water content, and geotechnical indices on GPR survey findings (Fig. 3).

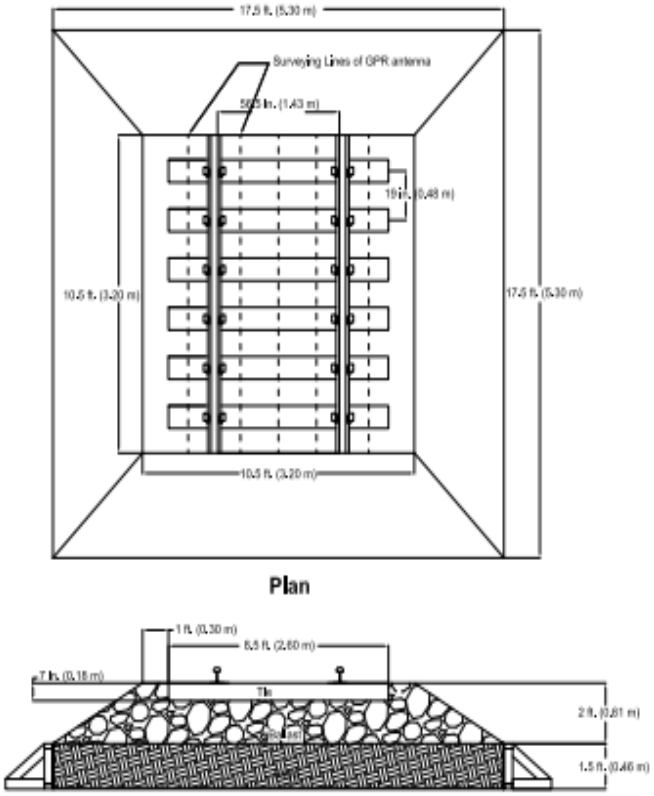

Figure 3: Schematic Plan and Section of a model track

Although all are accepted methods, the pulsed system method has been found to be the most accepted and used in most available equipment. GPR is most-commonly used for locating spacing and depth for reinforcing steel, posttensioning cables or anchors, measuring rebar cover, and mapping voids. With the growing availability and improvement of GPR processing software, research has found that it can be used as a subsurface condition assessment for FRP composites. GPR waveforms can now help detect voids inside the concrete. Compared to other nondestructive techniques, such as infrared thermography, ultrasonic or microwave, GPR offers more penetrating power and so can detect concrete defects or deteriorations at greater depths. Velocity (v) in the medium is given by the following equation:

v=cεr Where *c* is the velocity of electromagnetic waves in vacuum (=3 × 10^8 m/s) and ε_r is the relative dielectric constant of the propagation medium[9]. The depth of a subsurface interface or inclusion (*d*) can be obtained using the following equation: d=vt2 where *t* is the total round-trip time taken by the electromagnetic pulse to travel from the antenna to the subsurface feature and back to the antenna. Equations assumes that the radar antenna is placed on the surface of the test specimen and the same antenna transmits and receives the echo signal (pulse-echo mode). Since the waves attenuate as they propagate through a medium, it is customary to use linear or exponential gain (increasing with travel distance) during radar data acquisition[10]. The wave attenuation coefficient increases with antenna frequency and moisture content of the propagation medium (Halabe *et al*., 1993). While low-frequency antennas (15–900 MHz) are typically used for subsurface investigation in pavements and soils, higher-frequency antennas (1–2.5 GHz) are typically used in cases of concrete and composite structural components where the required penetration depth is much lower (few cm to 1 m). The higher frequencies offer shorter wavelengths and better resolution, so smaller defects can be detected [11].

LITERATURE REVIEW

Mario Quinta-Ferreira studies Ground Penetration Radar (GPR) offers a lot of potential in geotechnics, but it also has a lot of disadvantages. By enabling the gathering of field data in a fast and flexible way, this technique enables the connection between geological studies, geophysical characterization, mechanical exploration, and geotechnical zoning. The depth and accuracy of data gathering adapts easily to a wide range of conditions, from a few centimeters to many tens of meters, as well as the use of lower frequency antennas. This non-destructive, near-surface testing method may be used almost everywhere. The continuous data from the GPR complements the discrete and localized data from mechanical investigation. The use of direct mechanical examination and GPR imaging to validate local geological conditions allows for the confirmation of parameters obtained using different techniques, which, if verified, may allow for more accurate interpretation of areas and volumes. Under ideal conditions, the use of the GPR may greatly assist direct mechanical study, but interpretation must always be done with great care and based on a comprehensive knowledge of the site characteristics. The interpretation of the GPR is usually riddled with uncertainty.

The goal of the research was to increase the efficiency of geotechnical characterization by combining complementary techniques to reduce the cost and time required to perform geotechnical investigations while ensuring that the data obtained is suitable and sufficient for the desired goals. GPR was coupled with trenches and the Dynamic Probing Super Heavy (DPSH) test in a few case studies, allowing researchers to enhance the unique information of each technique while also taking the importance of each site's geology into account. In the geotechnical study for the rehabilitation of an ancient Villa, which required the construction of a small auditorium in the basement and an underground garage in the garden, the GPR and the DPSH successfully allowed to define the geotechnical zoning of the surface soils and the depth of the sandstone bedrock, as the local information obtained by the DPSH allowed to validate the GPR imaging. Hidden pipes and a subterranean water tank were also discovered using a GPR grid. GPR interpretation in karst areas may be challenging due to the uneven geological contact between the limestone and the residual soils inhabiting the dissolution zones. GPR imaging may frequently detect the layered structure and particle size variation in Aeolian sands, which can be verified by geological exploration and mechanical study. Aside from natural changes in the ground mass's electromagnetic properties, unexpected variables like tree roots, uncontrolled fill, or even previous excavations may make interpreting GPR data difficult [12].

Christopher Adam Senalik studies to detect objects in ground-penetrating radar (GPR) data, empirical mode decomposition (EMD) and dynamic temporal warping are employed (DTW). A total of two sets of wood specimens were evaluated. The first group consisted of laboratory-prepared Douglas fir (Pseudotsugamenziesii) wood pieces with known internal properties. The second set was made out of wood girders rescued from ancient Route 66 wooden bridges over an 80-year period. These two sets of specimens were scanned using the GSSI Subsurface Interface Radar (SIR) System 4000 with a 2 GHz palm antenna. Due to the presence of water, metal, or air inside the wood, GPR detected variations in dielectric constants (DC) throughout the scan route. The purpose of this research is to identify features and classify issues. The findings indicate that the techniques for presenting GPR data were effective [13].

DISCUSSION

This paper discusses about the twenty-first century, people may explore the deep ocean using underwater technology such as sonar, scuba diving, and other techniques, but mankind still has no clue what lurks beneath the earth's surface. To learn particular facts, one must either dig the soil or utilize the mining technique. We can penetrate the data up to 15 mm using electromagnetic radiation one of the electromagnetic radiation-based methods for investigating the earth's understanding is ground penetrating radar. GPR methods were first developed for oil and gas exploration, but they are now utilized in a wide range of disciplines, including

archaeology, environmental studies, geotechnical and hydrological investigations, and so on.GPR operates by delivering electromagnetic waves into the studied material (in the range of 10 to 10 000 Hz) and receiving the reflected pulses when they pass through discontinuities. A discontinuity may be a dielectrically different material's boundary or interface, or a subsurface object such a deboned or delamination. The amplitudes of the received echoes and their corresponding arrival times may then be used to identify the kind and location of the discontinuity. PR operates by delivering electromagnetic waves into the studied material (in the range of 10 to 10 000 Hz) and receiving the reflected pulses when they pass through discontinuities. A discontinuity may be a dielectrically different material's boundary or interface, or a subsurface object such a deboned or delamination. The amplitudes of the received echoes and their corresponding arrival times may then be used to identify the kind and location of the discontinuity. Velocities will vary based on the kind of material due to variations in electrical properties, and therefore generate reactions at different periods. As antennas move down the survey line, a series of traces are collected at certain places. After that, the scans are layered on top of one another to produce a profile of the area. The GPR's main components are a waveform generator, a single transducer with an emitting and receiving antenna, a signal processor, and a data storage/display device. Several techniques have been used for structural applications, including frequency modulation, synthetic pulse-radar, and pulse systems.

CONCLUSION

The complete procedure of identifying different utilities has been presented in this project. This procedure aids the client in locating different pieces of information under the earth. When a customer intends to develop buildings, malls, skyscrapers, and other structures without first learning about the underlying infrastructure, these utilities may be disrupted, causing major issues for the whole community. These GPR scans provide customers with information about the ground and assist them in constructing their structures in a well-facilitated location with utility pipelines. The most pressing issue we face today is water loss, which occurs when construction workers break water pipes without understanding what is underneath them. As a result, everyone is affected by water loss. In addition, the builder must pay a large sum of money to the government as a result of the loss. This effort will address the issue for the time being and in the future.

ABSTRACT

If left undetected, because of any leakage from gases or smoke, a lot of harm can be done to humans as well as non-living objects. This can trigger explosions in factories, manufacturing and areas in the vicinity. In remote areas, such as vents, pipelines, caves, where it is difficult for humans to patrol and track any gas leakage during the day and night, there may even be instances of gas leakage. Human beings detect leakage by two ways, one is the sound caused by leakage and the other is the odor created by gas. But these two methods, all the time and for a long time, are not successful and realistic. In this paper, an automated robot was built to detect any leakage of gas or smoke in the field. It has two operating modes. One is the way to avoid any obstacles and the other is the way to follow a predefined path. It will then detect any leakage and send the data to the personnel concerned for further action.

KEYWORDS:*Gas Sensors, Robot, Gas Leakage, Obstacle Avoidance, Line Follower, Autonomous.*

INTRODUCTION

Because of their widespread use with examples such as cooking and industrial usage, the use of flammable gases such as liquefied petroleum gases, methane, propane, i-Butane is growing with each passing day. But because of the leakage, this causes many incidents to increase. Such situations can often occur in which the gases or smoke from the pipelines or other connecting points can leak. Only by their smelling ability can humans detect leakage of gases, but this is possible only after the gas particles have blended with air and their concentration is high. If the workers walk along the pipeline route and notices any leakage, it is possible to monitor leakage from gas pipelines manually. However, any leakage will not be noticed throughout the day or night since the allocated personnel may only inspect for leakage according to the established timetable and report the patrolling results. If a worker discovers a leak of any gas and the source of the leak, they will raise a query and inform the staff, however this method has many hazardous elements. This whole operation should be carried out by a robot that will take the

place of humans in order to allow for the detection of flammable gas, monitoring of the leaking site, and prohibiting people from entering the area.

As a result, the paper's main focus is on a robot that can do the following tasks:

1. Patrolling the gas pipeline automatically according to a predetermined timetable.

2. Tracking any gas leaks and determining their stage of leaking.

3. Issue a warning to individuals in the area as well as others who are worried.

4. Take note of the gas ratio and save the information on a micro SDD memory card[1].

The proposed robot can operate in line follower and obstacle avoidance modes, distinguishing it from other generic robots [3]. The robot's distinctiveness has been attributed to its dual working mode and small size, which allows it to be deployed in distant locations to detect gas or smoke. In the mode of obstacle avoidance, it has the capacity to avoid any kind of impediment in its path, allowing it to travel freely throughout. The data is then wirelessly sent to the server. This mode is utilized when there is a need to check for leaks in pipelines, gas lines, or vents.

Fig 1: Automatic Gas Leakage Detector [2]**.**

As a result, it is capable of both determining its path and wirelessly delivering the signal. Alternatively, in line tracking mode, it follows the specified black line and detects any gas leakage, sending the required signal to the receiving mode. This mode is utilized when the robot must follow a predetermined path and then look for any gas leaks in that direction while performing the test [4]. Designing process: The development process has been divided into three steps:

1. Robot component parts design
2. Designing robot hardware modules
3. Computer design

The robot was designed to fulfill the following functions. It will conduct regular patrols beside the gas pipeline according to a predetermined timetable, and will do so while following the line alongside the pipeline. The gas pipeline would then be monitored by maintaining a record of the gas concentrations [4]. If the gas concentration was greater than the normal amount, a ringing alarm would sound and a light emitting diode would glow. The data collected will be kept for future research. It would be able to take a step forward, turn left and right, continue ahead, and dodge the robot line that would follow. bb. b. b. b. b. b. b. b. b. b. A wheel pair is put on the back side for forward motion, while one wheel is placed on the front as the driver's balancer. Internal components, such as a microprocessor, were put inside, while external components, such as LED gas sensors, were mounted on the body [5].

A line sensor is placed in the bottom portion of the robot because it must travel down the line. For power, a rechargeable battery is installed at the back. Creating hardware circuits: The components include a driver for motor L298N for controlling the DC motor, an Arduino Nana, and a TCRT5000 line sensor, a MQ-2 gas sensor that can detect flammable gases, an RTC DS3231 timer, a liquid crystal display, and a Micro SD Modulus [6]. The primary signal and data processor is linked to all of these components. A gas sensor detects the presence of any combustible gas and transforms it to a voltage equivalent that is sent to the Arduino Nano. The line sensor detects the black line and delivers voltage-adjusted resistance, which the microprocessor uses to drive the DC motor. The concentration of gas data is shown on the LCD screen, after which the data is stored on the memory card, followed by a robot stop or LED turn-on and buzzing warning. The RTC module is utilized for data recording and patrol scheduling. Combustible, flammable, and poisonous gases, as well as oxygen deprivation, may all be detected using gas detectors. This kind of gadget is extensively utilized in industry, and it may be found in places like oil rigs to monitor manufacturing processes and new technologies like photovoltaics. They may be used to battle fire [7].

LPG gas is detected using semiconductor sensors. The sensor is a MQ6 semiconductor sensor. The MQ-6 gas sensor's sensitive substance is SnO2, which has a reduced conductivity in clean air. The sensor conductivity rises in tandem with the increasing gas concentration when the target flammable gas is present. The MQ6 gas sensor offers a high sensitivity to Propane, Butane, and LPG, as well as a fast reaction time to Natural Gas. The sensor can detect a variety of flammable gases, including Methane; it is low-cost and appropriate for a variety of applications. The MQ-6 can detect gas concentrations of 200 to 10,000 parts per million. The output of the sensor is an analog resistance. The block diagram of the gas leakage detection and warning system is shown in Figure 1.

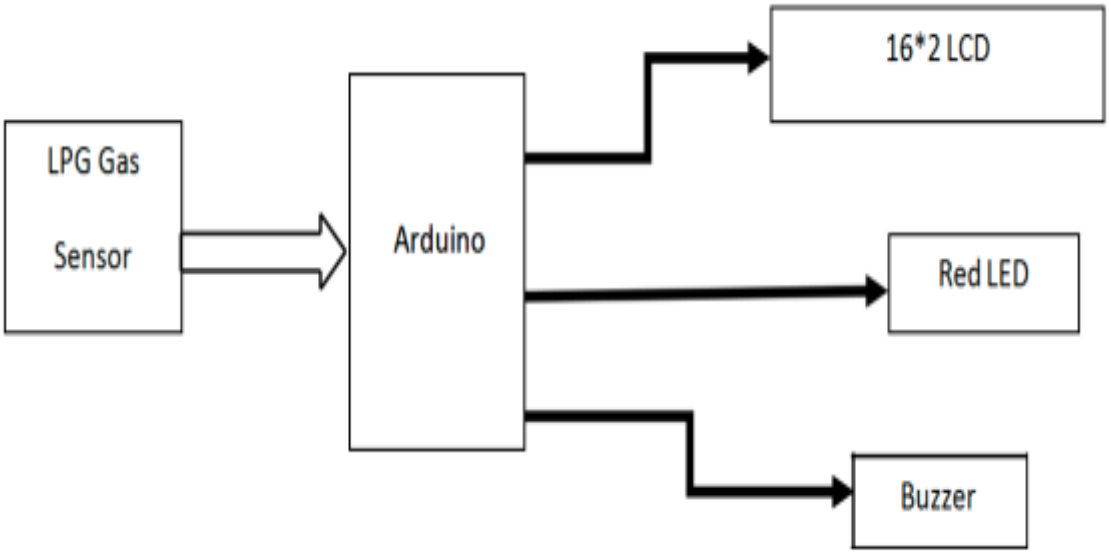

Figure 1. Block Diagram of Gas Leakage Detection and Alert System.

The Arduino UNO R3 and the MQ-6 gas sensor are used in this setup. If the sensor detects gas in the environment, it will produce digital output 1; if no gas is detected, it will output digital output 0. The sensor output will be received as a digital input by Arduino. If the sensor output is high, the buzzer will begin to tune, and the LCD will display "Gas detected: Yes." The buzzer will not tune if the sensor output is low, and the LCD will display "Gas detected: No." The buzzer is usually composed of a number of switches or sensors connected to a control unit that determines which button was pressed or whether a preset time has elapsed, and usually illuminates a light on the appreciate button or control panel, and sounds a warning in the form of a continuous or intermittent buzzing or beeping sound, and usually illuminates a light on the appreciate button or control panel. The following hardware components are needed for the construction of a sensor-based gas leakage detection and alarm system. The necessary hardware opponents, quantity, and pricing in Bangladeshi Taka are shown in Table 1. The gas detector is extremely inexpensive, costing just 917 BD Taka. The gadget is lightweight, portable, user-friendly, and efficient, with multi-functional capabilities. Figure 2 depicts the key components required for the design of a gas leakage detection and alarm system.

LITERATURE REVIEW

Writers HeruSupriyono and Ahmad NurHadi discussed the need for a wheeled robot to detect leaking of any gas or smoke in the robot's proximity. Other features have been added, such as line tracking and data transmission and storing to a micro SD card. Souvik Manna, Suman SankarBhunia, and Nandini Mukherjee addressed how to determine air quality as a consequence of increasing human-induced activities. The study monitored air pollution produced by automobiles, and IoT was suggested, coupled with a mix of electrochemical hazardous gas sensors and wireless sensor networks. The authors, Meer Shadman Saeed and NusratAlim, have proposed a new method for an autonomous robot to detect gas leakage that can operate in both obstacle avoidance and line mode using ultrasonic sensors and an infrared sensor. After then, a wireless signal is transmitted. Hiroshi Ishida, Keita Yoshikawa, and ToyosakaMoriizumi described an ultrasonic wave-based anemometer that could measure air flow direction in three dimensions and was surrounded by six semiconductor-based 3-D sensors. L298N engine driver, Arduino engine driver, Arduino engine driver Nano, Direct current motor, TCRT5000 line sensor, MQ-2 gas sensor, clock generator and RTC DS3231 timer, micro SD module, liquid crystal display, buzzing alarm, light emitting diode, and a battery as a power source are the various elements used to make the robot.

DISCUSSION

These paper discuses about the use of flammable gases such as liquefied petroleum gases, methane, propane, i-Butane is growing with each passing day. But because of the leakage, this causes many incidents to increase. Such situations can often occur in which the gases or smoke from the pipelines or other connecting points can leak. Only by their smelling ability can humans detect leakage of gases, but this is possible only after the gas particles have blended with air and their concentration is high. If the workers walk along the pipeline route and notices any leakage, it is possible to monitor leakage from gas pipelines manually. The robot was designed to fulfill the following functions. It will conduct regular patrols beside the gas pipeline according to a predetermined timetable, and will do so while following the line alongside the pipeline.

Keeping a record of the gas concentration would subsequently be used to monitor the gas pipeline [. If the gas concentration was greater than the normal amount, a ringing alarm would sound and a light emitting diode would glow.

A gas sensor detects the presence of any combustible gas and transforms it to a voltage equivalent that is sent to the Arduino Nano. The line sensor detects the black line and delivers voltage-adjusted resistance, which the microprocessor uses to drive the DC motor. The concentration of gas data is shown on the LCD screen, after which the data is stored on the memory card, followed by a robot stop or LED turn-on and buzzing warning. The RTC module is utilized for data recording and patrol scheduling. Combustible, flammable, and poisonous gases, as well as oxygen deprivation, may all be detected using gas detectors. This kind of gadget is extensively utilized in industry, and it may be found in places like oil rigs to monitor manufacturing processes and new technologies like photovoltaics. They may be used to battle fires. The Arduino UNO R3 and the MQ-6 gas sensor are used in this setup. If the sensor detects gas in the environment, it will produce digital output 1; if no gas is detected, it will output digital output 0. The sensor output will be received as a digital input by Arduino. If the sensor output is high, the buzzer will begin to tune, and the LCD will display "Gas detected: Yes." The buzzer will not tune if the sensor output is low, and the LCD will display "Gas detected: No." The buzzer is usually composed of a number of switches or sensors connected to a control unit that determines which button was pressed or whether a preset time has elapsed, and usually illuminates a light on the appreciate button or control panel, and sounds a warning in the form of a continuous or intermittent buzzing or beeping sound, and usually illuminates a light on the appreciate button or control panel.

CONCLUSION

The primary goal was to build a robot that could operate in two modes: one to avoid any obstacles in its path, and the other to follow a line and detect any gas leaks. As a result, a robot model for wheels was created to detect any gas escape. A gas-sensing device was also installed inside the wheel. The programming for carrying out all of the activities were shown in a flowchart for both modes of operation, and the relevant data was transmitted to the micro SD through the module if the ratio value was less than six. At a minimum of 5.92 cm, there is an abrupt halt, as indicated in Table 1. The robot's effectiveness has risen as a result of its two modes of operation, and it will be able to gather and transmit information about any gas or smoke leaks from a number of remote locations. An integrated device may be placed within the robot for future modifications that will detect and record the parts per million concentrations of the gas leaks detected. Other improvements, like as temperature sensors or wireless data transmission, may be made to improve the wheeled robot's capabilities.

ABSTRACT

Electric machines with permanent magnets are now being used in an increasing number of design methods. It is most importantly related to the development of novel long-lasting magnet materials (for example, Nd-Fe-B, a unique anisotropic combination) with high attractive exhibitions and relative ease of use. This research looks at contemporary permanent magnets. The attractive, warm, and mechanical characteristics of everlasting magnets, as well as their usefulness, are discussed in this article. This article also looks at places where everlasting magnets are used in many design fields.

KEYWORDS:*Permanent Magnet, Magnetic Materials, Alloys, Sm-Co, Nd-Fe-B, Magnetic Parameters, Magnetic Properties.*

INTRODUCTION

Magnetic materials are necessary for the world's people to have a good quality of life. Many of the gadgets we take for granted are made possible by them. The rising quality of life of people all over the world is posing raw material supply problems and spurring industrial innovation. We'll go through the basics of magnetic materials and how powder metallurgy plays a role. To comprehend the fascination with magnets, it's essential to go back at their history and identify what makes one magnet superior to another. We'll take a brief look at the series of events that led to the discovery of rare earth magnets, the most powerful magnets presently accessible. Then we'll go through a few magnet-related applications and why they're so essential to our economy, our way of life, and the fundamental foundations of our technology. Finally, we'll discuss the difficulty of producing enough of these strong magnets, as well as research into even better materials.

Future technologies for an electric and sustainable society will need a high level of material awareness. Several materials are thought to be essential for long-term sustainability. The effect of the rare earth element (REE) business on the environment may be seen at many stages of the process, including mining and refining. In the mining sector, the effect of other minerals found in the same deposit locations may be more important than the REEs themselves. Emissions may occur during milling, separation, or subsequent stages of processing the material into an usable metal.

Line I depicts the dynamic evolution of material characteristics of ferrite magnets used in latches.

Line 2 consists of magnetic Alnico alloys (Al-Ni), which are used in radio and television equipment.

Lines 3 and 4 relate to new types of magnetic materials that have been created using rare-earth metals: Sm-Co line 3 and Nd-Fe-B line 4 [1].

Figure 1 shows that the magnetic energy of samarium magnets is six to ten times greater than that of ferrite magnets. In reality, this implies that neodymium magnets with size comparable to an egg may cause finger shattering. That is the mechanical forces that are produced. Power, coercive power, heated solidity (up to 200 °C), and anti-consumption solidity Sintered magnets have a thickness of up to 8.5 gran/centimeter and a progress temperature of 700 'C. These characteristics indicate that Sm-Co is suitable for use in high-temperature or high-consumption environments.

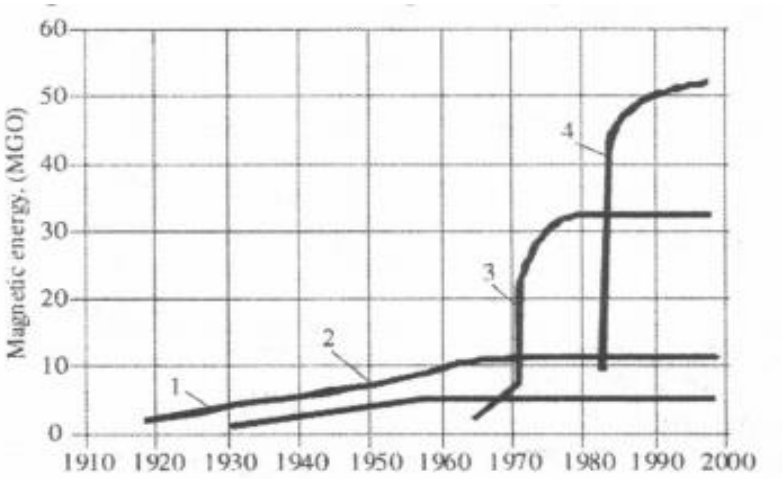

Fig 1: Shows That Behavior of Permanent Magnets Has Revolution Changes at Last Years

Direct alloying of initial components in a vacuum enlistment stove yields appealing mixtures with his characteristics [3]. Bullions bucks and smashes to a micron's worth of material. Magnets are ejected from a given residue in a variety of forms. Cakes made from stock material are baked at temperatures ranging from 1000 to 1200 degrees Celsius. The next item is mechanical handling, which includes hammering. Next, consider the benefits and disadvantages of various types of appealing materials. Strong mechanical strength, appealing characteristics strength across a broad temperature range, and high immersion force are the main areas of interest for alnico. These magnets, however, have very low coercive force. Ferrite materials have a strong coercive power, but they are also short and difficult to prepare. Similarly, a temperature has an effect on the attracting characteristics of such magnets [4].

As shown in Figure 1, there is a current focus in the area of PM research to bridge the performance gap between ferrite and RE magnets. It is proposed that a new magnet with an acceptable price/performance ratio of not more than approximately 1 $/J would be economically

efficient. A material with such characteristics may improve the performance and reduce the weight of existing ferrites-based devices, as well as lower the cost of RE magnet-based systems. Currently, bonded RE magnets, which are composites with PM powder incorporated in a plastic matrix, may cover the gap to some extent but at a significant cost. One way to bridge the gap between ferrites and NdFeB is to substitute less costly components for Nd. The cost-to-performance ratios of Ce-substituted NdFeB and SmCo compounds and alloys have been studied, and they show promise. Ce is a rare earth metal that makes up 66 parts per million of the earth's crust, compared to 41 parts per million for Nd. Uncommon earth magnets dependent on S m-Co composites have great attractive qualities (high immersion power and coercive power), warm strength and insusceptibility of consumption, moreover. The fundamental impediments are significant expense of a samarium and cobalt and thusly wide application of Sm-Co magnets is badly arranged. As of now, the most viewpoint sintered lasting magnets is Nd-Fe-B.

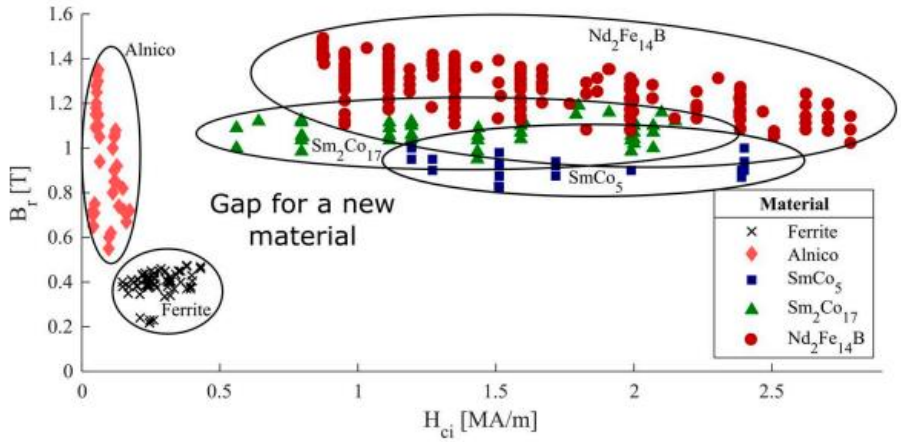

Figure 2. Different PM Materials Available On the Market and Their Properties, Illustrating the Gap between Ferrites and Rare-Earth (RE) Magnet.

To begin with, these magnets have most noteworthy BHmax and this worth don't reach limit.

Lasting magnets, compares powers, normally for regular machines and components (for example handfuls and hundred kilograms). At present in our nation, creation of uncommon earth magnets leaves out a research center stage and this creation are grown quick rate on premise of a adaptable innovation in a years ago. These days, such magnets are accessible for clients. Information of 000 "Chimcomplect" shows that lasting magnets Nd-Fe-B has special boundaries of qualities/cost. This clarify quickly a development of creation and presentation in different zones of designing such magnets [5].

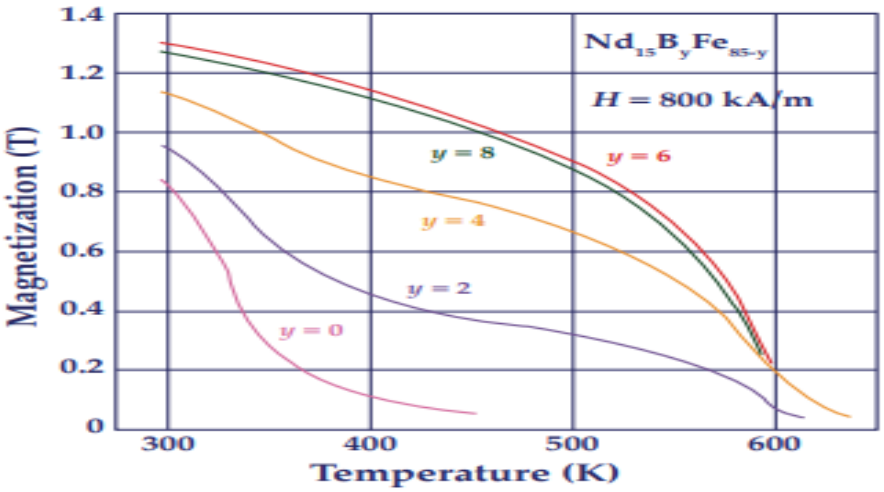

Figure 3: Magnetization vs temperature curves for H = 800 kA/m on five alloys containing different percentages of boron in Nd15ByFe85-y system.

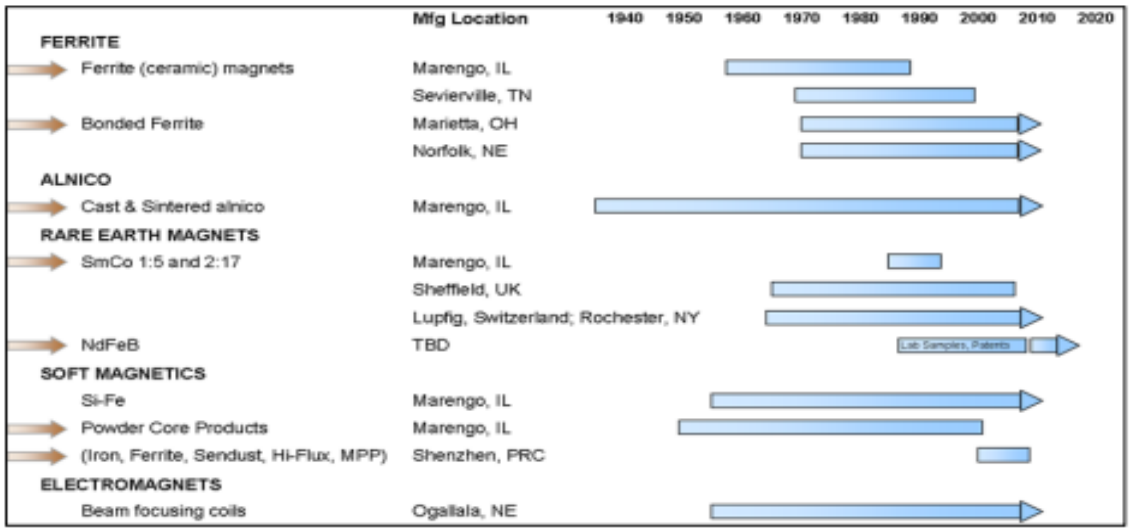
The magnetization versus temperature graphs for Nd15ByFe85y with y = 08 are shown in Figure 2. With rising temperature, the magnetization of the Nd15Fe85 binary alloy, which has around 0.8 T at room temperature, falls to a very tiny value at about 400 K. The Curie temperature of the NdFe alloy was predicted to be about 310 K based on a low field experiment. The alloy's magnetization rises as the amount of B added increases, peaking at approximately 6 atoms B. The development of a tetragonal phase with a high Curie temperature causes this rise. The Curie temperature of this phase was found to be 585 K using low field measurements. Arnold has amassed a vast knowledge base in a variety of materials over the past 70 years, including but not limited to those shown in Figure 1. Powder metallurgical manufacture is used to make the goods with tan arrows to the left. (Keep an eye out for these arrows; they'll be used throughout the text.) Arnold's product line-up and production sites have evolved as goods and markets have changed. Arnold has a unique insight and perspective on the magnetics sector because to his vast knowledge base.



REVIEW OF LITERATURE

Among all the papers published in the area of permanent magnet materials, Sergey Lutz discusses the use of unusual earth magnets to create tiny size and amazing devices with enduring

magnets in a paper titled "a review of modern materials of permanent magnets by Boris Bochenkov." The demand for long-lasting Nd-Fe-B magnets from Russian manufacturers is consistently increasing by 25-30%. In comparison to conventional ferrites, alnico, and other materials, the fundamental piece of leeway of magnets Nd-Fe-B and Sm-Co consists in great attractiveness of material characteristics at small scales. New types of magnets have more appealing characteristics while maintaining their size. It's worth noting that force power or tractive effort boosts recruiting appeal. On the other hand, it reduces measurement and weight while maintaining the force of the hardware. Using extraordinary magnets may sometimes result in a significant reduction in energy consumption. It's worth noting that force power or tractive effort increases the appeal of enlisting. On the other hand, it reduces measurement and weight while maintaining the force of the hardware. The use of ground-breaking magnets may sometimes result in a reduction in energy consumption. In the year 1970, an Alloy Sm-Co broad appears on the market. Sm-Co has a high immersion rate these days. Quite likely the most advantageous position consists of such materials in comparison to other appealing materials with relatively little effort. These materials also have a high appealing progress temperature, ranging from 160 to 170 degrees Celsius. Nonetheless, Nd-Fe-B magnets with an operating temperature of 200 °C are now available. This allows them to be used in electric engines with long-lasting magnets [6].

DISCUSSION

This paper discusses about the mechanical forces that are generated Power, coercive power, heated solidity (up to 200 °C), and anti-consumption solidity are all characteristics of this material. Sintered magnets may be up to 8.5 gran/centimeter thick and have a progress temperature of 700°C. Sm-Co is suited for usage in high-temperature or high-consumption settings based on these properties. In a vacuum enlistment stove, direct alloying of starting components produces attractive mixes with his properties. Bullions bucks and crushes material down to a micron's value. Magnets are expelled in a number of ways from a given residue. Temperatures ranging from 1000 to 1200 degrees Celsius are used to bake cakes manufactured from stock material. Mechanical handling, which includes hammering, is the third item on the list. Next, think about the pros and drawbacks of different attractive materials. The primary areas of interest for alnico are its high mechanical strength, attractive features strength over a wide temperature range, and strong immersion force. These magnets, on the other hand, have a very weak coercive force. Ferrite materials have a high coercive strength, but they're also short and tough to work with. Similarly, the attracting properties of such magnets are affected by temperature.

Uncommon earth magnets based on Sm-Co composites offer a lot of appeal (high immersion and coercive power), as well as warm strength and resistance to consumption. The main obstacles are the high costs of samarium and cobalt, which makes widespread use of Sm-Co magnets difficult. Nd-Fe-B is now the most widely used sintered long-lasting magnet. To begin with, these magnets have the highest BHmax, and this value does not exceed a certain limit. Magnets that last, compare powers, and are often used in ordinary machinery and components (for example handfuls and hundred kilograms). Currently, in our country, the production of rare earth magnets does not take place in a research center, and this production has expanded at a rapid pace as a result of a flexible invention a few years ago. Clients may now get their hands on such magnets. The data from 000 "Chimcomplect" reveals that long-lasting magnets Nd-Fe-B have unique quality/cost limits. This clarifies the evolution of invention and presentation in many design zones, such as magnets, rapidly.

CONCLUSION

After considering attractive, warm, and mechanical characteristics, it is reasonable to conclude that magnets made of rare earth elements are usually appealing. High-energy sintered magnets Nd-Fe-B are now being considered for use in the rotor of an electric motor. Furthermore, this study demonstrates that Sm-Co is suitable for use in high-temperature or high-consumption environments. Currently, take notice of the automobile industry's capacity to create expansions. The underlying problem in the automobile business is the ineffective presentation of new materials and technological advances. As a result, a requirement direction entails using today's appealing elements and advances. To begin with, it is linked to a large number of electromagnetic devices (ranging from 50 to 100). Controllability, economy, comfort, and various machine limits are all characteristics of this device. It's also worth noting the increase in power from 2 kW to 20-50 kW, which allows for the use of new amazing devices for supply management and monitoring. In this vein, global manufacturers are switching to a two-level voltage system (14 and 42V or 12 and 36V). Increased control requests for new appealing materials and new innovations of appealing materials (for instance: the multifunction starter, generator and so forth).

GENDER EQUALITY: SOME FEATURES OF INTERNATIONAL AND NATIONAL REGULATION

Burhanova L.M*

*Associate Professor,
PhD in Law,
Department of of Private Law, Specialized Branch,
Tashkent State University of Law, UZBEKISTAN

ABSTRACT

The article discusses the issues of legal regulation of equality of men and women in all spheres of life in the Republic of Uzbekistan on the basis of the norms of international and national legislation, which were carried out on the basis of the analysis of documents and research of international organizations, as well as the works of domestic and foreign scientists, using a set of methods: historical, comparative and others. The issues of the existing inequality of men and women are considered on the basis of a social-constructivist approach; in the interactions of people in public space; when considering practical problems, in particular, the gender division of labor, the representation of women in power structures. Theoretical proposals were made to improve the legal regulation of gender equality in the Republic of Uzbekistan on the basis of international and national legislative acts.

KEYWORDS:*Gender, Gender Equality, Gender Policy, Gender Identity.*

I. INTRODUCTION

In the Republic of Uzbekistan, a well-thought-out, legally defined gender policy, which represents measures of a legal, organizational and institutional nature taken by government agencies to eliminate the inequality of floors, achieve specific goals to ensure the actual or fundamental equality of women and men [1]. The term "gender" as a social aspect of the relationship between women and men, which manifests itself in all spheres of the life of society, including politics, economics, law, ideology, and culture, education, and science, education, and culture, education, and science, education, and culture, education, and science [1].

There is a well-established definition of gender affiliation as a set of signs of a person who determine its belonging to men either to women, mainly in cultural and social terms. Gender belonging is revealed through the roles defined by the Society, learned and expected models of behavior that are associated with men and women. When they talk about sexuality, they usually mean gender inequality - the conditions under which women and girls have fewer opportunities only because of their gender affiliation. However, the term "gender activity" also refers to boys

and men who are equally defined as such on the basis of the rights and social roles that the society has gone.

Unfortunately, humanity will have to go through a long way to achieve full equality of men and women in terms of their rights and opportunities. Legal protection against home sexual violence is deprived of over a billion women around the world. The gap of remuneration on the basis of sex is 23 percent in the world as a whole and comes to 40 percent in rural areas, and the importance of unpaid work that many women perform is not recognized. The share of women in national parliaments on average is less than a quarter, and in the board of directors - and less. Therefore, it is important to end with gender-based violence in all its manifestations, to ensure equal access of women of women and girls, men and boys to education, health care, economic resources and create equal opportunities to participate in political life. It also concerns employment opportunities in general and leadership positions.

Although women around the world have been conducted many studies proving that they do not lag behind men in terms of intellectual development and abilities, in many countries to women still do not belong as equal. Girls and women do not get the same rights, opportunities, responsibility and selection, which are considered to be inherent in men and boys from birth. Therefore, the consideration of the legal regulation mechanism, as well as the proposal of theoretical provisions on the improvement of legal regulation of gender equality on the basis of international and national legislation shows the relevance of the topic of this article.

II. Research Methodology.

In the course of the study, along with the general scientific dialectical method of knowledge, also part-scientific research methods were used - systemic, logical, comparative law.

III. Literature Review

In the Republic of Uzbekistan, the work of the legal regulation of gender equality is devoted to the work of Narbaev, because [2], Ganiyeva G. J. [3,4], Memecheva L.A. [5] and other authors who reviewed the issues of gender equality and the role of women in society. But in these works, gender equality issues were considered in the context of participation in the socio-political and economic life of the Republic of Uzbekistan. A comprehensive study on the legal regulation of gender equality on the basis of international conventions and agreements, as well as the laws of the Republic of Uzbekistan, was not conducted.

The issues of regulating gender relations of relations are considered in the works of foreign scientists, such as Chicalov I. R. [6], Sazds, E. A., Temkin A. A. [7], Andreeva G.M. [8], Burlin Sean [9], Vorontsov D. V. [10,11], Shevchenko L. A. [12], Kathy Davis, Mary Evans, Judith Lorber [13].

IV. Discussion and Analysis

Gender inequality is maintained in both the economic and political spheres. What topical issues are considered in scientific research of the existing inequalities of men and women at the present stage? First, the problem of creating a gender in the framework of the socio-constructivist approach. Secondly, the production of gender differences in the interactions of people in the public space. Third, practical issues: gender division of labor, women's representation in the structures of the government, the emerging structure of sexual and emotional relations, historical changes in structural models of behavior. The basis of these studies is to search for methods to eliminate inequality in the position of men and women in social practice and in the family.

The directions of such search are determined by international legal instruments on human rights, among which, first of all, be called the Charter of the United Nations. Among the objectives of the UN, stated in Article 1 of the Charter, it is proposed to "carry out international cooperation ...

In the promotion and development of respect for human rights and the main freedoms for all, without distinguishing races, gender, language and religion" [14].

The historical universal declaration of human rights, adopted by the General Assembly on December 10, 1948, confirmed that "all people are born free and equal in their dignity and rights" and that "every person must have all the rights and all the freedoms set forth in this Declaration without which It would be no difference in relation to race, religion or other position "[15].

In 1979, the General Assembly adopted the Convention on the Elimination of All Forms of Discrimination against Women (CED), which is often referred to as the International Bill on the Rights of Women. The 30 articles of the Convention gives a clear definition of the concept of discrimination against women and is proposed for an agenda for action at the national level, designed to put an end to such discrimination. The Convention considers culture and tradition as the influential forming of gender roles and family relations, as well as the first human rights treaty confirming the reproductive rights of women [16].

Five years after the conference in Mexico City, the Second World Conference on Women took place. The action program adopted on its outcomes contains a call to adopt more decisive measures at the national level to ensure the rights of women in possession and disposal of property, as well as rights regarding the inheritance, guardianship and loss of citizenship.

In 1985, the World Conference was held in Nairobi to review and evaluate the achievements of the decade of United Nations women: equality, development and peace. This event was characterized as "the birth of global feminism." Conscious that the goals of the conference in Mexico City were not fully achieved, representatives of 157 participating countries adopted Nairobian promising strategies in the field of improving the status of women for the period up to 2000. This document brought a gender aspect to a new level, proclaiming that it should be taken into account when considering all issues. The Fourth World Conference on the Status of Women, held in 1995 in Beijing, became another step forward from the moment of the conference in Nairobi. The Beijing Declaration and Action Platform confirms the commitment to specific actions to ensure the observance of women's rights.

On July 2, 2010, the Delegates of the UN General Assembly unanimously voted for the creation of a unified United Nations structure responsible for the acceleration of progress in achieving the objectives of the Organization related to gender equality and the empowerment of women. The new UN structure on the issues of gender equality and the empowerment of women called "UN-Women", united four divisions of the World Organization: the United Nations Foundation for Women's Development (UNIFEM), a department for improving the status of women (aux), office Special adviser to gender issues and improving the status of women and the International Research and Development Institution of the UN to improve the status of women (Munic).

Currently, all UN efforts are aimed at achieving recently adopted sustainable development goals (SDGs). In each of the 17 sch, women are assigned an extremely important role, and many tasks are directly aimed at recognizing women's equality and contribute to the expansion of their rights and opportunities both as a goal and as its achievement. So purpose number 5 directly consists in "providing gender equality and empowering all women and girls."

One aspect of the implementation of gender equality is to eliminate violence against women. The UN system still pays special attention to the issue of violence against women. In 1993, the General Assembly of the Declaration of Eradicating Violence against Women is determined by the definition of violence against women and a clear statement of rights to ensure the eradication of violence against women in all its forms [17]. The Declaration reflected the determination of

states to fulfill its obligations and the commitment of the international community as a whole to efforts to eradicate violence against women.

International Women's Day is celebrated on March 8. On this day, women are noted, regardless of national borders or ethnic, linguistic, cultural, economic and political differences. The idea of holding an international women's day first emerged at the beginning of the twentieth century, when an industrially developed world experienced a period of expansion and shocks, demographic boom and the appearance of radical ideologies.

To ensure compliance with the rights of women around the world, many States will have to make appropriate changes to national legislation. The standards ensuring the equality of men and women are enshrined in the standards of the Constitution of the Republic of Uzbekistan, the Civil Code of the Republic of Uzbekistan, the Family Code of the Republic of Uzbekistan, the Labor Code of the Republic of Uzbekistan and a number of other laws and regulatory legal acts.

Special laws adopted, ensuring the equality of men and women - the Law of the Republic of Uzbekistan "On Guarantees of Equal Rights and Opportunities for Women and Men" and the Law of the Republicof Uzbekistan "On the protection of women from oppression and violence."

The Law of the Republic of Uzbekistan "On Guarantees of Equal Rights and Opportunities for Women and Men" provides for the concept and types of gender equality. In particular, it is given a definition of direct discrimination on the basis of gender, which implies any difference, an exception or limitation that is sent to non-recognized women and men of their rights and freedoms in all spheres of life of society, including discrimination due to marital status, pregnancy, family duties. , as well as sexual harassment, various pay for equal work and qualifications. The law contains the definition and indirect discrimination on the basis of sex as the creation of a situation, the provisions or criteria that are placed by the individuals of the same sex at a less favorable position compared to the persons of the other sex, including the propaganda of gender inequality through the media, education, culture, the establishment of conditions or Requirements that may entail negative consequences for persons of a particular floor [1].

The basic principles of ensuring the guarantees of equal rights and opportunities for women and men in the Republic of Uzbekistan are the legality, democracy, equality of women and men, the inadmissibility of discrimination on the basis of gender, openness and transparency.

The law provides for guarantees to ensure equal rights and opportunities for women and men. The state guarantees women and men equality in the implementation of personal, political, economic, social and cultural rights. The state guarantees women and men equal participation in the management of the affairs of society and the state, the electoral process, ensuring equal rights and opportunities in the field of health, education, science, culture, labor and social protection, as well as in other spheres of state and public life. In order to achieve actual equality between women and men, expanding their participation in all spheres of society, the elimination and prevention of direct and indirect discrimination on the basis of gender by the state are made temporary special measures to ensure the implementation of gender policies.

The law provides for guarantees of equal rights and opportunities for women and men in various spheres of public life, as well as responsibility for violating legislation on the guarantees of equal rights and opportunities for women and men.

The Law of the Republic of Uzbekistan "On the protection of women from oppression and violence" includes provisions that determine the types of oppression and violence in everyday life, at workplaces and educational institutions; the tasks and functions of authorized bodies on countering oppression and violence against women; measures aimed at preventing oppression

and violence, as well as responsibility for the commission of such actions; Procedural guarantees of pre-trial and trials aimed at protecting persons undergoing oppression and violence [18].

In terms of practical actions, in order to prevent gender discrimination, the Commission for the Protection of Gender Equality of Women, with the assistance of the Committee of Women of the Republic of Uzbekistan, whose main tasks are defined:

- Active participation in the implementation of state policies aimed at ensuring gender equality and improving the social conditions of women in the country;
- Consideration of applications of state bodies and other organizations on violations of gender equality of women;
- Development of proposals for implementing generally accepted international norms into national legislation to eradicate all forms of discrimination against women's rights.

V. DISCUSSION AND CONCLUSION

In the modern world, gender issues and the struggle for women's equality, the subject of active discussion is not only scientists, but also in society as a whole. The motor of this attention is the active position of female movements. Obviously, further regulatory work on gender equality should rely on and based on international legal instruments on human rights. First of all, the UN Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), since the Convention contains specific recommendations, which should be done to make states for practical elimination of inequality of men and women at the present stage. Essentially, States are invited to a specific action program in this area.

In the Republic of Uzbekistan, it is advisable for this, firstly, the adoption of measures for the practical implementation of the principle of the equality of men and women. It is possible to do this in the course of planning, developing and implementing special documents, in the development of special provisions - criminal, procedural and executive steps of new editions of codes.

Secondly, to fully take advantage of the possibility of encouraging inclusive work with non-state stakeholders in the field of gender equality.

Thirdly, it is advisable to develop and adopt the concept of family and gender policies in the Republic of Uzbekistan, where it is important to clearly distinguish between the tasks of the family policies and the tasks of gender policies in order to prevent the role of women in the family sphere. To do this, it is necessary to clearly distinguish the goals, objectives and indicators of gender equality policies and family policies. While the family policy can be used as a tool for performing gender equality problems, gender equality policies need to be considered as a comprehensive and multifaceted strategy that goes beyond family issues, and concerning all aspects are relevant both for women and for men, As, for example, family support measures, it is important to ensure that specific objectives relating to the empowerment of women in politics and the economy have been clearly allocated.

Thus, it can be concluded that ensuring consistency of the vision and policy of ensuring gender equality in the Republic of Uzbekistan is associated with the general vision of the country's development, as well as with state policy measures across various sectors and levels of power, in order to develop gender equality in all spheres of life.

ARTICLE EXPRESSION OF INDEFINITENESS MEANING IN ENGLISH AND UZBEK LANGUAGES

Mehmonova Yulduz*

*Lecturer,
Department Translation Studies and Language Education,
Bukhara State University, UZBEKISTAN

ABSTRACT

This article is dedicated to the article expression of indefiniteness with lexico-grammatical parts of words in English and Uzbek languages. The expression of indefiniteness of the articles in the system of different languages with lexico-grammatical parts of words have been analyzed and its similarities and differences are determined.

KEYWORDS: *Indefiniteness, Article, Lexico-Grammatical Units, Context, Nouns, Definite, Indefinite, English, Uzbek.*

INTRODUCTION

In modern English, the category of indefiniteness is mainly given by special markers, indefinite articles - a (an).Counting numbers served as the source of the indefinite article, so in these languages, where a system of articles still exists, there is a formal and semantic similarity between the indefinite article and the countable number.The article indicates that the object represented by the name belongs only to this class of objects.

I saw a dog – Men itni ko`rdim, (qanaqadir bir itni) aynan itni, mushukni yoki boshqa biror narsani emas.

In English, an article is the primary means of expressing indefiniteness. Indefiniteness is expressed by the method of opposition: an apple - the apple.In English, the article does not represent other grammatical categories such as rod, consonant, and so on.

2. Main part:

In English, the function of an article is primarily to express the subject, to show that the word used with them is a noun, not a group of words. The article indicates that the noun belongs to the category of accuracy - uncertainty, expressing a number of characteristics that are specific to the noun.According to V.N.Yarseva, "the article is connected with the noun as a group of words, but does not belong to the paradigm of the noun, because it does not participate in the characterization of the meanings that connect the noun with other members of the phrase" .Indefiniteness is represented in every way. It depends on the structure and type of each specific national language.

Depending on whether the abstract level is morphologically developed or not, indefiniteness can be expressed by special prefix morphemes. In addition, the place of the article is determined by the various cases in which the structure of speech is in the general orientation of the constitutions of all its constituents.Thus, the article is represented at the following specific levels of the language hierarchy: morphological, lexical, and syntactic. However, this does not mean that every language has units at all these levels. In some languages, ambiguity is expressed more morphologically, in other languages lexically, and in some languages syntactically. In this regard, the English language is associated with a greater lexical level. However, the other levels were not distinguished in terms of indefiniteness.

In the future, we will be convinced that we have found models with a sense of indefiniteness that act as syntactic constructions.The lexicon of indefiniteness is related to the development of the article.In Old English, the indefinite article did not exist as an independent word group. Later, the English language system itself created such a set of words.So there is a need for an article in the language. If we proceed from the diachronic development of the indefinite article, it has the following dynamics.

In the middle Ages, an indefinite article appears in English. As in other languages, the unstressed variant of that number comes from "one". Then the vowel sound was reduced to the unstressed state and a different unstressed variant was formed.

In Old English, the number "a" took on the form "on" after the long "a" changed to the open "o"; The difference in sounds between the accented and unaccented forms caused the article to be separated from the number.Later, this exchange in the number was abolished, and the form "on" was used in all cases. The exchange of "a" and "an", which are forms of indefinite article, depending on how the next word begins, has survived to the present day.

In English, the number "an" has changed both semantically and phonetically, while the number "bir" in Uzbek has changed semantically, not phonetically. On this basis, "one" remains as a semi-article.A similar historical path has been traversed by the indefiniteness of the Turkish language. This number several linguists consider «one» as an article. It is important to note the difference between the indefinite article in English - a (an) and the number "one" in Uzbek.

He was saving his money to buy a car (BARS).

Ehtimol bir kun borib yarashardik (A.Muxtor, Chinor, 171).

Based on this example, as well as on the basis of materials of other languages, a unique typological conclusion can be drawn: if the language develops an analytical system associated with the complete or partial disappearance of forms of agreement, it accelerates the emergence of articles, or otherwise in other words, this process creates additional conditions for the emergence of articles.It is necessary to point out several assumptions about the development of the article, that is, the emergence of an ambiguous article in English may have been caused by a phono morphological change in the English language.For example, the disappearance of many grammatical prefix morphemes in English has accelerated the development of articles in English. This is emphasized in the comparison of the English language system with the Uzbek language system. At the same time, the developed agreement paradigm, which at the same time has the expression of the contractual relationship, includes the function of nouns used in conjunction with vague and definite articles: *Give me the book. - Menga kitobni bering.Give me a book. - Menga kitob Bering.* In the above examples, the function of the indefinite article is given by omitting the Uzbek suffix.

Indefiniteness in English is mainly expressed by the morphological indicator - the indefinite article - a (an), which is the main indicator of this category and has the highest level of

ambiguity.Other units in the Uzbek language are also considered, as there is no article in this language and the category of indefiniteness is represented by various means.

In the Uzbek language, the function of expressing indefiniteness is performed by several suffixes belonging to different word groups and semantic classes, which mainly represent other categories, but at the same time also serve to express indefiniteness.These include comparisons, diminutives, word-formative forms of modality, and others with their own prefixes - roq, - gina, - kina, and so on.*"Why didn't select a nice subject?" – She was saying. (J.London, "Martin Eden", 118). – Nega chiroyliroq mavzu tanlamadingiz? - dedi qiz. (Jek London, "Martin Iden" 118). I tought you were a crazy girl. (Hemingway, "A Farewell to Arms", 109). Menga sal telbaroq bo`lib ko`ringan edingiz. (E.Heminguey, "Alvido Qurol!", 164). I was a little crazy. (Hemingway E., "A Farewell to Arms!", 109). Ozgina telbaligim ham yo`q emasdi. (E.Heminguey, "Alvido Qurol!", 164). A little , she said. (Hemingway E., "A Farewell to Arms!", 117). Jindakkina, - dedi u. (E.Heminguey, "Alvido Qurol!", 168).*

Indefiniteness - the morphological category of accuracy is not expressed in all languages, where it is expressed in syntactic forms. If this category is expressed in several languages by word forms, in other languages it is expressed by auxiliary words. Even if the article is expressed by auxiliary words, it belongs to the morphological category. Like other morphological categories, the article covers nouns entirely and can be studied as one of the indicators of this word group.

In a number of languages, it performs the formal function of expressing the syntactic connection of a noun with a noun. This process occurs either in the adaptation of the article, or under the influence of the word system. The morphological nature of the article thus does not cause any hesitation.The physical existence of articles is not universal. For example, there is no article in Russian. "In another case, through the use of an article, the listener is warned that the cognate noun distinguishes one or more of the many abstract nouns, and that it is not the general concept of the subject but the actual subject that is singled out. This task, which can be called a highlighting task, is performed using an indefinite article" (68, 220).

In languages where the article does not exist, the task of highlighting the subject is performed by various means.Thus, the purpose of the situational actualization of the concept of subject in the Uzbek language is, first of all, "one, somehow, somehow" (of which "somehow, somehow" means to show that the subject is not well known to the speaker) They do it themselves.Thus, an article is a morphological category, regardless of whether it is expressed by a prefix or an auxiliary word.

In English, the category of precision and ambiguity has a grammatical character. This is the definite article - the and the indefinite article - a (an).The semantic structure of an indefinite article includes:1) the specific meaning of the classification related to the subject to which it belongs belongs to the class of this or that subject:*a dog - it (har qanday bir it)* 2) nouns with the meaning of uniqueness, indefinite article "a (an)" are always used in the singular:*a book (any single book), an apple*3) the meaning of indefinitenessClassification"A (an)" is unique

Indefiniteness

In contrast to English, the category of definiteness and indefiniteness in Uzbek has morphological and lexical meanings. "Somehow, somehow, something" corresponds to the indefinite article on all functions performed by the pronouns and the number "one".Based on this, we can say that the article is an indicator and a marker of accuracy and uncertainty. In this case, the articles with the above meanings remain the central unit. However, it should be noted that there are other decentralized units that represent the same function. Many languages have them all, while others have some of them.

CONCLUSION

1.Indefiniteness is a category of different types, that is, typological means belong to different word groups: articles, nouns, numbers, rhymes, forms, connectives, modal words, and so on. Each category has its own characteristics, that is, some express the indefiniteness in the implicit way, while others express it in the explicit way. This proves that indefiniteness is common to all word groups. In English the main marker of indefiniteness is the article, and in Turkish such a function is represented by the number "one". These ideas prove that the process of converting a number into an article in English has been completed, and in Uzbek this process is still going on. In both languages being compared articles and other word groups constitute the main group of means representing the category of indefiniteness. Repetitive words in the languages being compared play an important role in the expression of the selected category.

ABSTRACT

The purpose of this paper is to study and discuss the topic of creating ontologies using Semantic Web Mining, which is described as a mix of the two rapidly expanding research fields of Semantic Web and Web Mining. The Semantic Web is the second-generation WWW, supplemented by machine-processable information that assists the user in his duties. Web mining is the application of data mining techniques to the content, structure, and usage of Web resources.This can aid in the discovery of global and local structural "models" or "patterns" within and across Web pages, as well as the extraction of ontologies. The automatic or semi-automated development of ontologies, which includes extracting the related domain's words and connections between such concepts, and encoding them using an ontology language for simple retrieval. Because manually creating ontologies is very time-consuming and labor-intensive, there is a strong need to automate the process. This paper provides an outline of where the two fields now intersect, as well as suggestions for how a tighter integration may be beneficial.

KEYWORDS: *Knowledge Discovery, Ontology, Ontology Learning, Semantic Web, Web Mining.*

14. INTRODUCTION

Because it is one of the newest and most forward-looking media, and undoubtedly the medium of the future, the Internet is becoming increasingly essential for virtually everyone.Because of unstructured online contents and a lack of standards, the extraction of valuable knowledge from the Web is becoming increasingly challenging. This complexity in the treatment and extraction of data is developing. Large-scale data knowledge Web pages make information difficult to utilize. In the recent decade, a slew of ways have been developed that integrate data mining and knowledge discovery methods with Semantic Web data. The objective of these techniques is to

aid various data mining activities or to improve the Semantic Web as a whole. All of these techniques fall into one of three major categories:

- Supporting knowledge discovery with Semantic Web-based methods, Semantic Web Technologies, and Linked Open Data.
- Mining the Semantic Web with data mining techniques, also known as Semantic Web Mining.
- Creating and improving Semantic Web data using machine learning approaches.

Tim Berners-newest Lee's effort, the Semantic Web, is an expansion of the present Web that makes it simpler to locate, exchange, reuse, and combine information[1]. It is built on machine-readable data and draws on the capabilities of XML technology to establish unique tagging schemes as well as RDF's (Resource Description Framework) flexible approach to data representation. The Semantic Web establishes standard data transfer formats. It also provides a common language for recording how data relates to real-world objects, allowing a person or machine to start with one database and then move through an infinite number of knowledge databases to find various concepts and words to build ontologies and representations in a way that all users can understand and consume.

In order to extract relevant and shared knowledge, this study will outline the similarities of the two fields.

14.1. Basic Definitions:

14.1.1. Ontology:

Ontology explicitly defines the words used to describe and represent a body of knowledge. People, databases, and applications that need to exchange domain information utilize ontologies. Ontologies are computer-readable descriptions of the domain's core ideas and their relationships. They may store both domain-specific and cross-domain information[2].

An ontology, in more technical terms, is made up of classes, connections, and characteristics. An ontology's classes are generic entities that exist in a variety of fields of interest. The names of classes are usually nouns. The relationships exist between the items; in this study, we utilize two relationships: ‘part-of' and ‘is-a.' The properties or attributes are the qualities or characteristics that objects can have.

Let's start with an example of an ontology and its representation, as shown in Fig. 1.

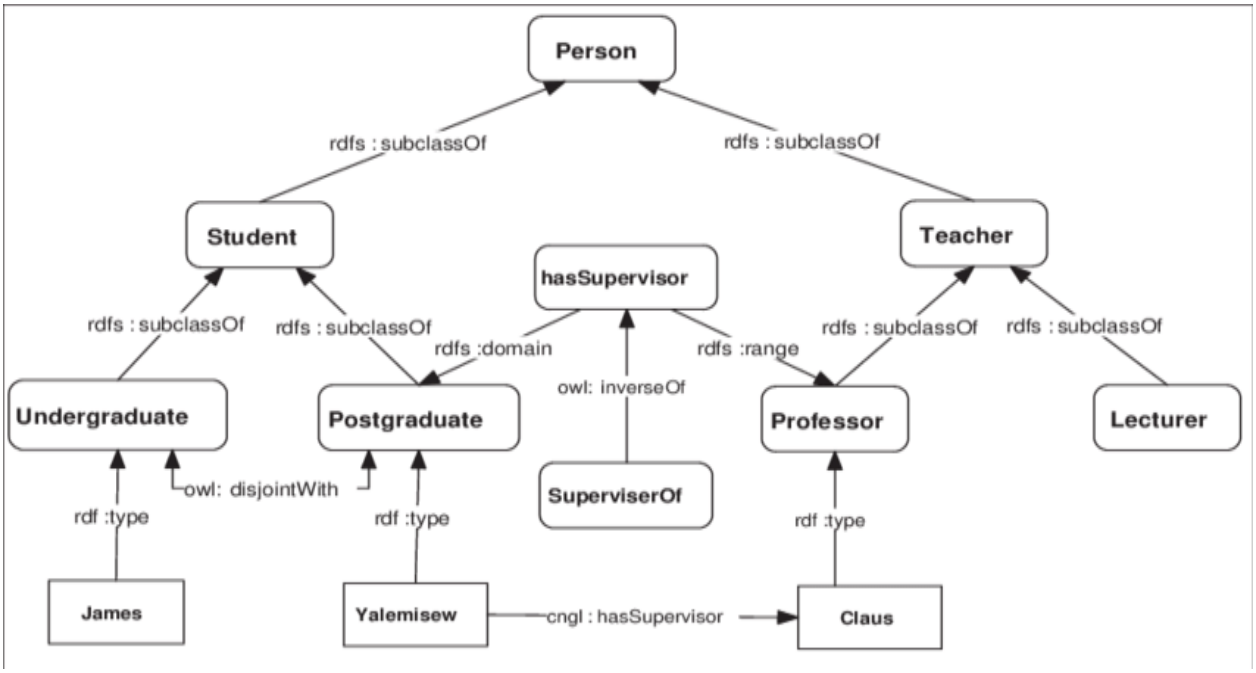

Fig. 1: Example of an ontology- The University Structure[3]

14.1.2. Semantic Web Mining:

On the one hand, human ability to comprehend information is limited, but the amount of available information on the Web grows rapidly, resulting in rising information saturation. In this environment, detecting valuable trends in the Web and using it as a rich source for data mining becomes increasingly crucial.

The Semantic Web Mining study area aims to combine two rapidly expanding disciplines of research: the Semantic Web and Web Mining[4]. The goal is to enhance Web Mining results by utilizing new semantic structures in the Web on the one hand, and to use Web Mining to build up the Semantic Web on the other side. These two categories address one of the World Wide Web's (WWW) current challenges: utilizing Semantic Web technologies to convert unstructured data into machine-understandable data.

Because the Semantic Web adds formal semantics to the first generation of the WWW, it provides a solid foundation for Web mining: The sorts of links or hyperlinks are now fully specified, allowing the knowledge engineer to get deeper insights into Web structure mining; and the contents of the pages are now accompanied by a formal semantics, allowing mining techniques that need more structured input to be used.

14.1.3. Semantic Web Content and Structure Mining:

Content and structure are inextricably linked on the Semantic Web. As a result, there is no longer a distinction between content and structure mining. The distribution of semantic annotations, on the other hand, may give extra implicit knowledge. The methodologies presented as Relational Data Mining, originally known as Inductive Logic Programming(ILP), are an important collection of techniques that may easily be applied to semantic web content or structure mining[5]. In a relational database, relational data mining looks for patterns involving many relations. It includes Semantic Web Mining methods such as classification, regression, clustering, and association analysis. It is quite simple to adapt the algorithms so that they can cope with data defined in RDF or via ontologies.

This endeavor faces two major scientific obstacles. The first is the amount of data to be processed, i.e. the algorithms' scalability, and the second is that the data is dispersed over the

Semantic Web because there is no central database server. For ILP algorithms, scalability has always been a key problem. With the Semantic Web's projected expansion, this problem will only get worse. As a result, the mining algorithms' performance must be enhanced, for example, by sampling.

14.1.4. Semantic Web Usage Mining:

Usage mining can be improved much more if the semantics are included clearly in the pages by referencing to ontology topics. For example, semantic web use mining may be done on log files that record user activity in terms of an ontology. The AIFB has created a mechanism for generating such semantic log files from a knowledge portal. These log data may then be mined to give customized perspectives of the ontology, such as clustering people with similar interests.

15. DISCUSSION

15.1. The Knowledge Discovery Process:

The five phases in the process model for knowledge discovery lead from raw data to actionable information and insights that are of immediate use to the user. Fig. 2 depicts the entire procedure. There are five steps to it:

i. Selection:

The first stage is to gain a thorough understanding of the application domain, capture important prior information, and determine the data mining aim from the perspective of the end user. The target data utilized in the knowledge discovery process may be chosen based on that understanding, which includes picking appropriate data samples and a relevant subset of variables.

ii. Preprocessing:

In this phase, the selected data is processed in such a way that it may be analyzed later. The management of missing values, the detection and possible repair of noise and mistakes in the data, the elimination of duplicates, and the matching, fusion, and conflict resolution for data from many sources are all common activities done in this stage.

iii. Transformation:

The third stage transforms the data into a format that data mining algorithms can understand in most situations; this involves converting the data into a propositional format, with each instance represented by a feature vector. Dimensionality reduction techniques can be used in this phase to minimize the effective number of variables under consideration, which will increase the performance of following data mining algorithms.

iv. Data Mining:

Once the data is in a usable format, the process's original aim is assigned to a specific method, such as classification, regression, or clustering. This step entails determining which models and attributes are appropriate (models for categorical data differ from models for numerical data, for example), as well as matching a specific data mining method to the KDD process's overall criteria (for instance, the end user may prefer an interpretable but less accurate model versus a highly accurate but difficult to interpret model). Following the selection of the data mining technique and algorithm, the data mining process begins: looking for patterns of interest in a specific representational form or set of depictions, such as rule sets or trees.

v. Evaluation and Interpretation:

The validity of the patterns and models produced by the data mining algorithms is checked in the last phase. In addition, the user evaluates the usefulness of the discovered knowledge in the

context of the program. This stage can also include visualizing the extracted patterns and models, as well as visualizing the data using the models.

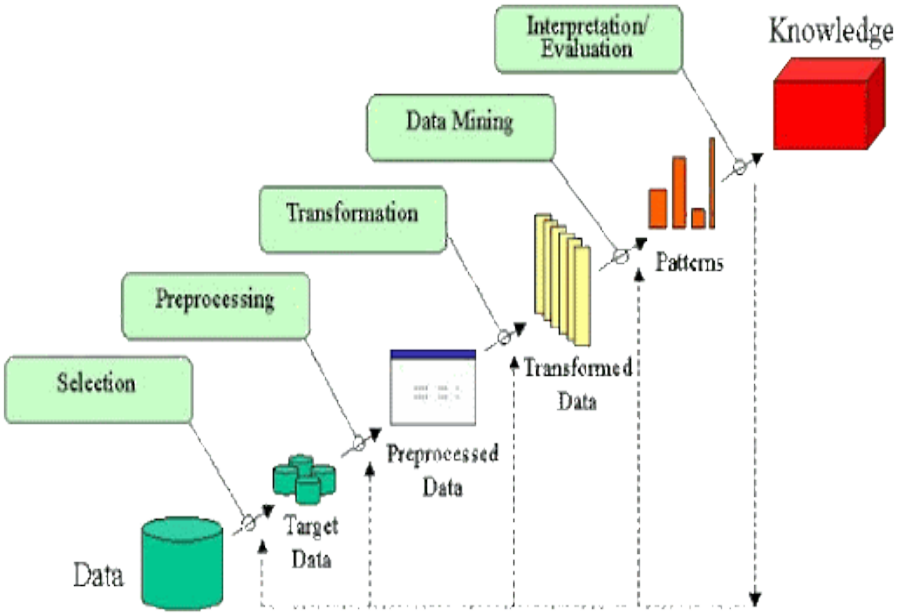

Fig. 2: Process of knowledge discovery [6]**.**

15.2. Ontology Learning Process:

Ontology learning is a technique for extracting entire ontologies from natural language text or Web pages automatically or semi-automatically. The method is generally broken down into the eight steps below, but not all of them are required in every ontology learning system.

i. Domain Terminology Extraction:

Domain specific words are retrieved during the domain terminology extraction stage, which are then utilized to derive concepts in the next step. Relevant words can be found, for example, by calculating TF/IDF values or using the C-value / NC-value technique. A domain expert must next filter the resultant list of keywords. The OL system then identifies synonyms, similar to how the IE system decides co-reference resolution, since they have the same meaning and so relate to the same idea. Clustering and the use of statistical similarity metrics are the most frequent approaches.

ii. Concept Discovery:

Terms are organized into meaning carrying units that correspond to a simplification of the world and thus to concepts, in the concept discovery stage. These domain-specific words and their synonyms were found in the domain vocabulary extraction stage and are grouped together.

iii. Concept Hierarchy Derivation:

The OL system attempts to organize the retrieved ideas in a taxonomic framework during the concept hierarchy generation stage. Unsupervised hierarchical clustering techniques are commonly used to achieve this. Because the output of such approaches is frequently noisy, a level of oversight, such as user assessment, is incorporated. Another technique for constructing a concept hierarchy is to employ a number of patterns that should suggest a subsumption or supersumption connection. X is a subclass of Y, as shown by patterns like "X, that is a Y" or "X is a Y." Such patterns can be effectively examined, but they are far too rare to extract sufficient sub- or supersumption connections. Instead, bootstrapping approaches are being developed, which automatically learn these patterns and therefore assure a better level of coverage.

iv. Learning Of Non-Taxonomic Relations:

Relationships that do not express any sub- or supersumption are retrieved during the learning of non-taxonomic relations phase. Works-for and located-in are two examples of such connections. There are two typical methods for completing this subtask. The first is based on the extraction of anonymous relationships, which are then given suitable names in a subsequent phase. The second method removes verbs that show a connection between the items represented by the surrounding nouns. However, an ontologist must assess the outcome of these techniques.

v. Rule Discovery:

Axioms or formal descriptions of ideas are created for the retrieved concepts during rule discovery. This can be accomplished, for example, by evaluating the syntactic structure of a natural language specification and applying transformation rules to the dependency tree that results. This procedure produces a list of axioms, which is then translated into a concept description. An ontologist will have to assess this one.

vi. Ontology Population:

The ontology is supplemented with examples of concepts and attributes during the ontology population stage. Methods based on the matching of lexico-syntactic patterns are utilized for the augmentation of ideas with examples. Application of bootstrapping techniques, which gather relation tuples, adds instances of properties.

vii. Concept Hierarchy Extension:

The OL system aims to expand the taxonomic structure of an existing ontology with new concepts in the concept hierarchy extension stage. This may be done either supervised with the use of a trained classifier or unsupervised with the use of similarity measurements and shown in Fig.3.

viii. Tools:

DOG4DAG is a plug-in for Protégé 4.1 and OBO-Edit 2.1 that allows you to create ontologies[7]. It has the ability to generate terms, siblings, definitions, and relationships. DOG4DAG is an ontology extension tool that is built into Protégé 4.1 and OBO-Edit 2.1. It supports all popular ontology formats, including OWL and OBO[8], [9]. The lookup service additions are mostly limited to EBI and Bio Portal. Users may express clear, formal domain models using OWL ontology languages. They meet all of the fundamental criteria for ontology languages, including:

- Convenience of expression
- Efficient reasoning support
- Formal semantics
- Well-defined syntax

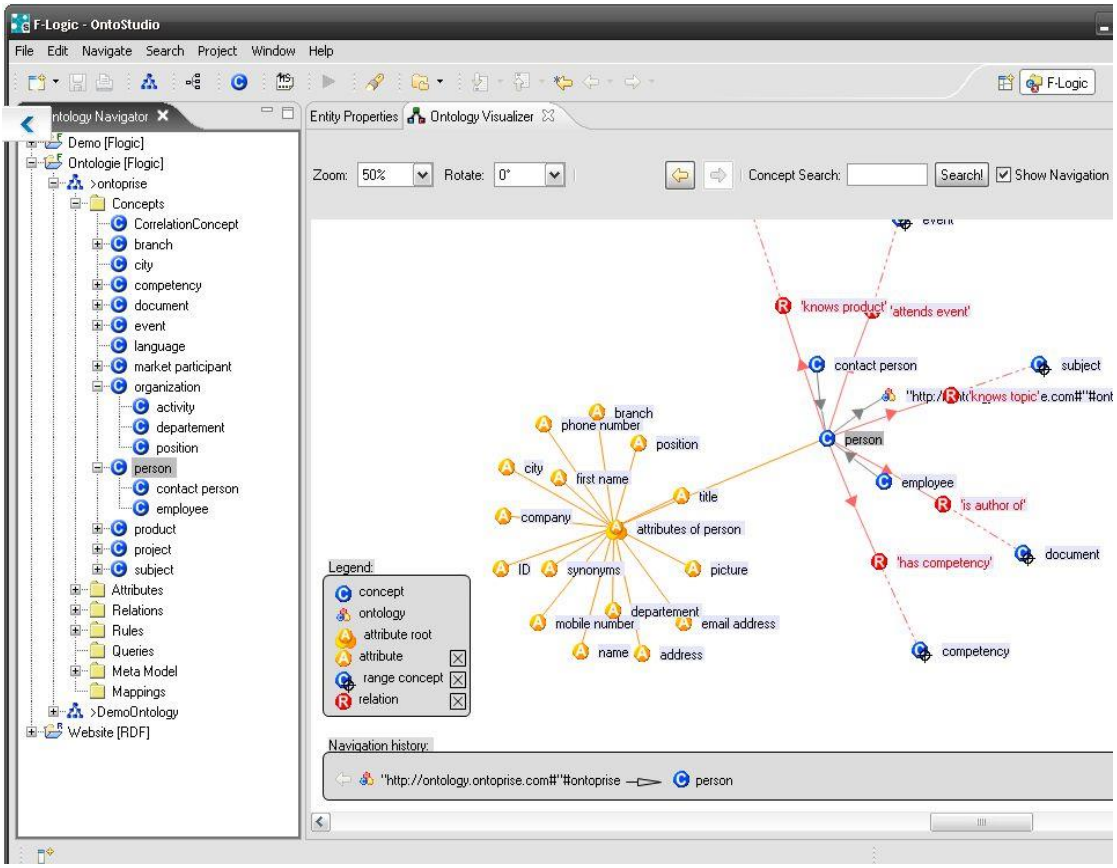

Fig. 3: Illustrates building ontolgy example with ontoStudio[10]**.**

The OWL and RDF subclass relationship attribute OWL is based on RDF and RDF schema, and it utilizes the XML-based syntax of RDF. OWL may be defined using XML-based syntax, Abstract RDF-based syntax, or Graphical Syntax. The proposed architecture was used to create an ontology based on a web log that was defined using the web ontology language (OWL). This program will assist web writers by evaluating user browser history of web sites that are often frequented by people and the products that are popular in the market. Web structure mining has been used to assist with the development of ontologies and the retrieval process.

16. CONCLUSION

The usage of ontology in Web mining is summarized in this article. We pay special attention to how ontology has been integrated into Web mining. We spoke about how Semantic Web Mining can enhance Web Mining results by using new semantic structures in the Web, as well as how Web Mining methods may be used to build the Semantic Web.To comprehend and change the Web, we anticipate Web Mining techniques to progressively handle content, structure, and use in an integrated manner in iterated cycles of extracting and using semantics. We anticipate to see a fruitful complementarily between those depending on semantics in the sense of the Semantic Web and others relying on a broader definition of semantics among those iterated cycles.

ABSTRACT

Agriculture is one of India's most vital sectors, and it is critical for the country's economic survival and development. Agriculture is the source of livelihood for about 70% of households and 10% of the urban population. Today, India is the world's biggest exporter of agricultural goods such as coffee, tea, rice, oil meals, spices, meat, fresh fruits and vegetables, as well as their preparation and marine products. The Indian Agriculture Research System is the pinnacle of a process that began in the nineteenth century and culminated in the creation of the ICAR (Indian Council of Agricultural Research) in 1929, after the recommendation of a Royal Commission on Agriculture. In the present research system, the Indian-Council-of-Agriculture-Research (ICAR) primarily assists, promotes, and collaborates on research and education in India at the national level. Because farmers strive to feed the globe with limited natural resources, technological advancements are critical to the future of farming. The agri-tech solution contributes to the overall expansion of sustainable agriculture and food production. Agri-tech startups and disruptive market newcomers are the focus of the funding. Agriculture output increases as a result of new technology, resource input, and economic incentives. Future food-production and handling technological development should be non-polluting, minimize environmental and health risks, and not inspire additional governmental restrictions.

KEYWORDS:*Agriculture, Economic, Environment, Innovation, Sustainable.*

1. INTRODUCTION

Agriculture is the most common land use on the planet. Approximately 1.2 billion–1.5 billion hectares are now under cultivation, with 3.5 billion hectares grazed. Agriculture is India's economic powerhouse, and it plays a critical part in the country's social and economic domains. Productivity, economic viability, environmental effect, and social well-being are the four major sustainability indicators for agricultural production. The biggest problem in today's situation is to provide an adequate food supply for the world's population. The environmental impact of agriculture (Figure 1) on ecosystems in different agricultural practices and how that influence may be linked back to the agriculture practice. Agriculturing's environmental effect varies widely depending on the farmer's methods and the size of such operations. Sustainable-Agriculture techniques are agri-practices that try to reduce environmental effect by changing the practice [1], [2].

Natural resource scarcity, climate change, and food waste are the major factors putting strain on the agricultural model's ability to meet future requirements. All of these factors are exacerbating the issue of hunger and food shortage. Experts employ two kinds of indicators when evaluating the environmental impact: mean-based, which is reliant on the grower's production technique, and effects-based, which is the influence of farming methods on the agricultural system. The superiority of groundwater that is influenced by the amount of nitrogen in soil is an example of a mean-based approach. The indicators used to identify Nitrate damage to groundwater are "effects-based." The farmer's agriculturing practice is examined in a means-based evaluation, whereas the actual impact of agricultural practice is examined in an effects-based assessment. Farmers employ a “mean-based” pesticide and fertilizer analysis technique, while an “effect-based” evaluation analyzes how much carbon dioxide is released and how much nitrogen is present in the soil [3], [4].

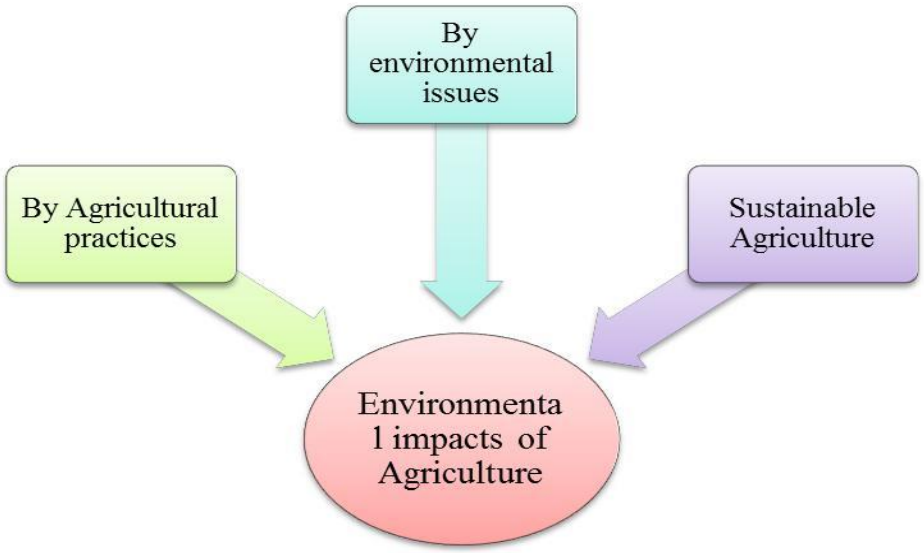

Figure 1: Illustrates the environmental impacts of agriculture in different Agriculture Practices.

Agriculture's environmental effect includes a range of factors such as soil, air, water, animal & soil-variety, plants, humans, and the food itself. Agriculturists contribute to a slew of environmental issues, including climate change, irrigation, genetic engineering, soil pollution, and waste. Sustainable agriculture is the concept that agriculture should be conducted in such a manner that we can continue to produce what is necessary without jeopardizing future generations' capacity to do so. In recent decades, rapid population growth has boosted agricultural land conversions to meet food demands, which has had a negative impact on the

environment. Agriculture has the potential to have a detrimental effect on biodiversity. Organic farming is a multi-faceted, long-term agricultural technique that has the least environmental effect on a small scale. In terms of production/unit/area, organic farming produces less. To achieve the same level of production, organic farming requires more land to be cleared and water resources to be removed. Governments, investors, and new agricultural technology will need to work together to address all of the problems [5]–[7].

Technological applications to agricultural production are seen to be the answer to meeting the growing population's food needs. To meet the need of a fast growing population, agricultural output requires a 70% increase in production, as well as successful expansion in harvesting, distribution, and resource intake. There are many innovations in the field of information and communication technology that may be used to the agriculture sector in areas such as precision agriculture, farm management software, agricultural equipment, and wireless sensors. Precision agriculture techniques rely heavily on remote-sensor technology. The study uses an aerial-vehicle to capture pictures, process them, and analyze them, highlighting technological advancements in agriculture. For our country's economy to grow from agriculture to emerging states, agricultural development is insufficient. Agriculture development and non-farm sector development are inextricably linked. For example, farming provides food, its processed materials, and labor, whereas the non-farm sector provides products and services in rural areas.

Agriculture and farm operations will have to be managed in a completely different way as technology advances, such as gadgets, sensors, machinery, and information technology. Temperature and moisture sensors, robotics, ariel pictures, and GPS technologies will all be used in future agriculture.

The sophisticated gadget and robotic-system will enable the farm to be more environmentally friendly, productive, and safe. New technology innovation is a key driver of socioeconomic growth, particularly ecofriendly breakthroughs that boost output while simultaneously maximizing the efficient use of natural resources. Through diverse processes, the employment of various technologies in agriculture increases growth and development with effective production. Rural-development has been able to reduce poverty as a result of the following effects of technology usage and innovation. The primary objectives of the agricultural sector are to increase production and increase farmer income.

2. IMPACT OF TECHNOLOGY ADVANCEMENT

The use of innovative technologies in the global economy is a defining element in the race and has a significant effect on agriculture. Innovation is a key driver of social and economic development, especially environmentally friendly innovation that boosts output and promotes efficient natural resource management. The concepts and notion of agricultural sustainability, with a focus on genetic improvement through contemporary ecological methods and better understandings as a result of ecological and scientific-agricultural organization, redesign, and modification. The explanation for the rise in interest in agriculture's long-term viability. People interested in ecologically friendly and healthy farming, as well as those concerned about their economic and social dimensions, use the phrase "sustainable agriculture." The concept of sustainable agriculture refers to agriculture's final goal, which may allow it to fulfill requirements on both sides of the spectrum. According to reports, the agriculture sector must re-establish itself based on the principle of sustainable agriculture, which increases agricultural effectiveness. The re-established use of the sustainable-agriculturing principle and proper respect for the region's social, economic, and environmental characteristics are required. The connection between organic farming and other alternative agricultural methods. To those who do not believe that sustainable agriculture is necessary to signal the end of large-scale farming, and who value

the sector's ability to continue to provide food for a city-population that has little or no contact with agriculture producers, stricter regulations and standard protection are critical [8], [9].

Agricultural sustainability has been limited completely to the quest for potentially more sustainable agriculture methods in the future. These methods have also focused on the present crop and animals in each producing region. All sustainability criteria, such as resource conservation, environmental preservation, and farming in harmony with nature, will increase rather than decrease world food supply. There are about 570 million farms in the globe, while financing cycles in technology-innovation in agriculture have grown by almost $570 million in 2014. While most of the investment is going into agri-tech startups and disrupting the market for newcomers, the need for innovation in resource usage, particularly in terms of land, water, and energy, is still very much there for increasing competence and profitability.

Agricultural's scope has been broadened by the expansion of the agriculture food sector and its integrated supply chain, as well as globalisation, high-tech and economic advancements, and environmental impacts. In addition, previous global economic crises have shown a lack of applicability and durability of the current-growth model and agricultural strategy. New-structural solution is thus needed. Apart from all other considerations, the modern-growth-theory views technological advancements as tools for economic development. This technological application will significantly contribute to the expansion of the countryside and the reduction of poverty. Science, engineering, and technology advancements are key tools that assist to achieve the above-mentioned objectives and bring about the improvements.

Innovation is a fantastic concept that encompasses more than just technology. Innovation is a process in which a person or organization introduces new/existing goods, processes, or organizational methods for the first time. Agriculture encompasses the whole value chain, from agricultural, fisheries, forestry, and livestock production to input and resource management, as well as market access. Innovator was founded by the American Seed Trade Association (ASTA) and the Biotechnology Innovation Organization (BIO). This unique forum will elicit a serious and thoughtful debate about food and agricultural innovation, as well as the actual benefits it brings to our world, health, and food. Farmers may use scientific data and technology to improve crop yields and stay current with cutting-edge agricultural methods.

The use of ag-tech to agricultural output is critical to meeting the growing population's food need. To meet the requirements of a rapidly expanding population, agricultural productivity must increase by 70% in manufacturing and improve proficiently in harvesting, consuming, and resource distribution. Inventions in information and communication technology that may benefit the agricultural sector in many areas of sustainable agriculture, such as the use of farm-management software, agriculture equipment, and wireless-sensors. In order to farm sustainably, remote-detection technology is critical. Agriculture output will increase as a consequence of new technology, increased source effort, and lucrative inducements. Food processing and other high-tech advances should be non-polluting, reduce environmental risks, and not rely on new regulatory forms.

3. ADVANCEMENT IN TECHNOLOGY

Advancement in technologies are the future of agriculturing because farmer make every effort to feed all over the world with inadequate natural resources.

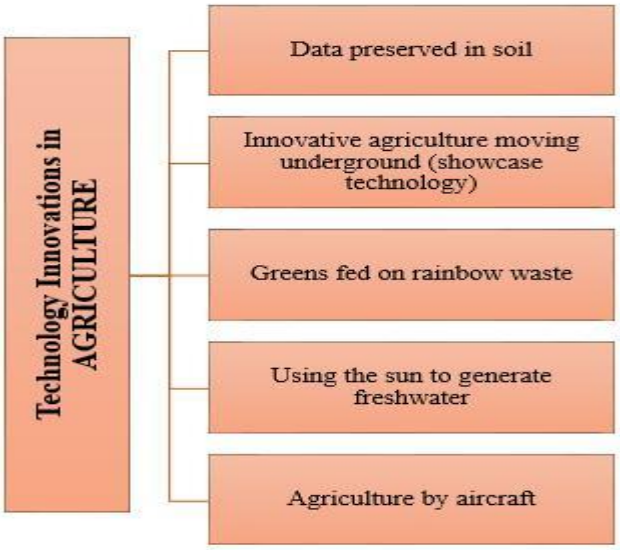

Figure 2: Illustrating the Advancement in Technological Innovation in Agriculture

Agriculture productivity will rise as a consequence of new technology, resource input, and economic incentives. Future technology advancements in food processing and other activities must be nonpolluting, minimize environmental risks, and not inspire additional regulatory controls. The study's main focus is on resource innovation in terms of land, water, and energy, with the goal of increasing effectiveness and yield [10]. Figure 2 depicts five ag-tech startup technologies that may help the world's growth of sustainable agriculture and food handling:

3.1. Data that has been preserved in the soil:

The main need of traditional agricultural models is the availability and suitability of land. By combining new analyses, field experiments, statistics, and crowd-sourcing, the African-Soil-Information-Services (AFSIS) is developing soil-maps. The key to planning sustainable agricultural growth and natural resource management is innovative farming ideas like digital soil mapping. All of these maps are freely available to be examined on Google Earth.

3.2. Innovative underground agriculture:

Compared to conventional agriculture, subterranean agriculture offers a lot of benefits. By being inside a big metropolis, farmers can provide fresh food to a huge metropolitan market. They don't have any pests, so they don't have to use pesticides, and the weather is never an issue. The use of technology in agriculture promotes development and expansion via active manufacturing processes. Hydroponics-based cultivation progresses at double the rate of traditional cultivation. A special LED lighting gadget is utilized in this procedure to speed up the photosynthesis process.

3.3. Green waste rainbow fed:

Embracing a moral circle of exchange is a common agricultural idea. Hydroponics is a technique of growing plants that utilizes mineral-enriched water. In an aquaponics recirculating system, fish farming and plant growing are combined. Fish provides nearly all of the plant's nutrition in the form of aquaculture sewage, which is separated from fish waste metabolites by direct absorption and nitrification by plants in properly maintained water, and then returned to the fish. When compared to conventional horticulture agriculturing, this revolutionary farming concept uses less water. At Bioaqua Farming (Blackford) in Somerset, one of Europe's largest combined aquaponics farms, vegetables are produced and Rainbow Trout are reared in an organic

association without the use of chemicals or pesticides, instead relying on the assistance of bees and worms.

3.4. Solar-energy generation of fresh water:

The primary trend in agriculture is to improve water efficiency in farming and food production. The argument is that despite the fact that water covers 71% of our globe, there is still a shortage of water. Sundrop Farms is one of the agricultural inventions that makes use of a rare renewable resource that is abundant in comparison to seawater: sunshine. Sundrop Farm collects solar energy to provide energy for purifying and hydroponics greenhouse supplies. When compared to traditional greenhouse production, sundrop farms minimize reliance on limited natural resources.

3.5. Airborne agriculture:

The agricultural sector is increasingly reliant on aircraft. Crop dusting, fertilizer spraying, pesticide distribution, topdressing, and hydro-seeding are all common uses for agricultural aircraft. In the agricultural industry, crop dusting is also known as aerial application, and it is one of the keys to contemporary efficiency in agriculture. Such aircrafts must improve their efficiency, cost-effectiveness, environmental compatibility, and safety. Traditional fuels and tube wing designs are the only options for aircraft design.

4. DISCUSSION

Innovation is a key driver of social and economic development, especially environmentally responsible innovation that boosts output and makes better use of natural resources. As the world's political, economic, and environmental conditions change, innovation is currently supporting higher values in organic raw materials in a series-processing, packing, storage, transportation, and distribution of food after production and food safety. As a result, the use of equipment in farming accelerates growth and development by allowing for effective production via a defined procedure. Over time, the application of technology and creativity may have resulted in a reduction in poverty in rural areas. A conceptual framework for modernization, primarily for the utilization of machinery, must be developed. In terms of R&D and scope, the farmer must clearly understand how the development and implementation of inventions will allow for potential agricultural impacts. The aim of R&D should not be restricted to a certain proportion of budget allocation. It should be recognized that science's contribution to society is one of the most important foundations for sustaining agricultural output.

Increasing agricultural production, increasing farmer income, reducing poverty, and expanding rural areas are not insurmountable objectives. Growth in income among small farmers and corporate businesses, as well as in the agricultural sector and food chain, would result in a substantial increase in social benefit in the nation. To improve efficiency and reduce poverty in rural regions, comprehensive and inclusive research and strategies are needed. Taking action has become authoritative in light of the well-organized utilization of natural resources, food security, and the effects of climate change. Various technical advances, including as sensors, machines, gadgets, and information technology, will need farm houses and agricultural operations to be managed in a completely different manner. Moisture, robotics, Ariel pictures, temperature sensors, and GPS technology will all be used in future farming. These gadgets and robotic structures will make farming more environmentally friendly, cost-effective, efficient, and secure.

High-tech agricultural output is a way to meet the growing population's food needs. To meet all of the needs of a rapidly increasing population, agricultural productivity must increase by 70% in making levels and improve proficiently in harvesting, marketing, and resource intake. Various innovations in the field of information and communication technology that may benefit the agricultural sector in the fields of precision agriculture, farm management software, wireless sensor technologies, and agriculturing equipment technology. Precision agriculture makes

extensive use of remote detection equipment. The article examines how precision agriculture is influencing agricultural practices via the use of aerial vehicles for imaging, handling, and inspection. Because farmers are attempting to feed the whole globe with limited natural resources, technological innovation is critical to the future of agriculture.

Agriculture output will increase as a consequence of new technology, source effort, and economic inducements. Future high-tech advances in food processing and other activities should be non-polluting, reduce environmental risks, and not be accompanied by additional regulatory forms. The significance of this research is the invention of new land, energy, and water sources that increase efficiency and productivity. There are five high-tech solutions that are helping to support the global expansion of sustainable farming and food manufacturing: preserved data in the soil in the form of maps, underground agriculture innovation using hydroponics with LED lighting for photosynthesis, greens fed on rainbow waste without chemicals or pesticides, use of the sun to generate freshwater via Sundrop farms, and a new crop of greens fed on rainbow waste without chemicals or pesticides. Agricultural development has been influenced substantially by technological advancements throughout time. Humans have discovered a new method to make agriculture more effective and produce more food by developing a tool to Global-Positioning-System (GPS) centered on precision-farming gear. A technological revolt in farming is being steered by advances in robotics and detection technologies, which seem to be on the verge of disrupting current methods. Automation and robotics, vertical indoor farming, livestock technology, precision agriculture, up-to-date greenhouse practice, artificial intelligence, and block-chain technology are all examples of major space technology advancement.

5. CONCLUSION

In current agricultural techniques, innovations are more important than ever. The agricultural sector is facing significant difficulties, including workforce scarcity, increasing supply prices, and shifting customer preferences for transparency and sustainability. Cultivation businesses are increasingly aware that a solution is required to address these issues. The advantages of indoor-vertical-farming are numerous, ranging from sustainable urban-growth to capitalizing on agricultural production with low employment expenses. Vertical farming can control factors like humidity, light, and water to precisely measure year-round, resulting in constant food production. Farm robotics, often known as "smart farming," is a kind of technology that allows farmers to automate the crop/livestock production cycle. Drones, self-driving tractors, automated watering, robotic harvesters, and seeding robots are all being developed by a growing number of businesses. Industry is now experiencing unprecedented growth, thanks in large part to amazing recent technological advancements. Today's greenhouses are large-scale, capital-infused, and urban-focused. The objective is for the farmer to use artificial intelligence to accomplish his or her aims of a higher crop by making better field decisions.

ABSTRACT

Improving the accuracy of renewable energy forecasting is important to power system planning, management, and operations as renewable energy becomes more prevalent in the worldwide electric energy grid. Due of the sporadic and unpredictable nature of renewable energy data, this is a difficult job. To date, a variety of approaches have been developed to enhance the forecasting accuracy of renewable energy, including physical models, statistical methods, artificial intelligence techniques, and their hybrids. Deep learning has been widely described in the literature as a potential form of machine learning capable of finding intrinsic nonlinear characteristics and high-level invariant structures in data. This article offers a thorough and in-depth examination of deep learning-based renewable energy forecasting techniques in order to assess their efficacy, efficiency, and application potential. Deep belief network, stack auto-encoder, deep recurrent neural network, and others are the four categories of extant deterministic and probabilistic forecasting techniques based on deep learning. To enhance forecasting accuracy, we also analyze viable data pre-processing approaches and error post-correction procedures. Various deep learning-based forecasting techniques are thoroughly examined and discussed. Finally, we look at present research efforts, problems, and future research goals in this area.

KEYWORDS:*Deep Learning, Deterministic Forecasting, Machine Learning, Probabilistic Forecasting, Renewable Energy.*

INTRODUCTION

Fossil fuels are still the world's most significant source of energy today. Hydrocarbons or its derivatives, such as coal, oil, and natural gas, are examples of fossil fuels. Fossil fuels take millions of years to produce, and existing stocks are destroyed far quicker than new fossil fuels are created. Simultaneously, fossil fuels produce greenhouse gases, which exacerbate climate

change such as global warming, putting people's livelihoods in jeopardy. As a result, renewable energy has received a lot of attention in recent years all around the globe [1]. Solar energy, wind power, tidal energy, and geothermal energy are examples of renewable energy that can be recycled in nature. Renewable energy offers at least two benefits over fossil fuels. To begin with, renewable energy resources are plentiful and renewable across the globe, and they are unrenewable. Second, renewable energy is clean, green, and low-carbon, making it good for environmental protection [2].

In particular, renewable energy can efficiently decrease sulfide (SO_2), carbide (CO), and dust emissions, lowering the danger of air pollution and the greenhouse impact. Furthermore, the usage of renewable energy may help to decrease the use of natural fossil fuels while also achieving the goal of environmental protection. Furthermore, renewable energy may help to decrease solid waste discharge and therefore soil contamination. Renewable energy may help decrease waste gas and waste liquid emissions during usage, thus meeting the goal of water resource protection. As a result, renewable energy has exploded in popularity in recent years. Renewable energy accounted for 19.3 percent of worldwide energy consumption and 24.5 percent of power production in 2016, according to REN21's 2017 report. Many nations, including the United States and China, have created regulatory measures, incentives, and subsidies to promote the use of renewable energy. Although renewable energy is seen as the most promising alternative to fossil fuels because it is clean, green, and naturally replenished over a large geographic area, it also introduces uncontrollable uncertainty, which jeopardizes energy system reliability and stability, particularly with large-scale renewable energy integration [3].

On the one hand, renewable energy is characterized by high volatility, intermittent nature, and unpredictability, all of which will certainly raise the reserve capacity of electric energy systems, raising the cost of power production. The utilization of renewable energy, on the other hand, necessitates a high number of power electronics, which lowers the power system's rotational inertia and therefore diminishes the system's stability margin. As a result, renewable energy forecasting as an effective tool for reducing associated risks is critical for electrical power and energy system planning, management, and operation [4]. Due to the intermittent, chaotic, and unpredictable character of renewable energy data, reliable renewable energy forecasting remains a difficult job. Various methods for providing accurate renewable energy forecasts for the next few minutes to the next few days have been described in the literature. Physical approaches, statistical models, artificial intelligence techniques, and their hybrid methods are generally classified into four groups. Numerical weather prediction (NWP) models, which simulate atmospheric dynamics based on physical principles and boundary conditions, are used in physical techniques [5]. Limited area models, such as the fifth-generation mesoscale model and high resolution fast refresh, are included in NWP models, as are global models, such as the global forecast system and integrated forecast model.

Temperature, pressure, jaggedness, and orography are only a few of the climatic and geographical variables that go into NWP. Physical techniques are effective in predicting atmospheric dynamics, but they need a lot of computing resources since they require a lot of data to calibrate [6]. This becomes much more problematic when physical techniques make unanticipated mistakes during prediction. As a result, physical techniques are ineffective for predicting with short time horizons. Statistical models are used to discover the mathematical connection between online renewable energy time series data. In the literature, the auto regressive moving average, Bayesian method, Kalman filter, Markov Chain model, and gray theory were extensively used. A novel wind energy forecasting system based on the Hammerstein model was created, capable of finding various asymmetric distributions, non-stationary profiles, and chaotic dynamics. For deterministic and probabilistic wind power

forecasting, the authors developed a Bayesian-based adaptive robust multi-kernel regression model[7]. To achieve the time-series prediction of wave energy, a Kalman filter and time-varying regression technique were suggested in. The case study demonstrates that the suggested approach provides the most accurate predictions.

However, the majority of current statistical models for renewable energy forecasting are linear models, limiting their capacity to handle increasingly difficult prediction issues with longer forecasting time horizons [8]. Due to their prospective capacities for data-mining and feature-extracting, artificial intelligence-based forecasting models constantly offer a more promising performance than physical methods and statistical approaches as soft-computing techniques advance. To manage the nonlinear connection between input and output through error reduction, support vector machines, artificial neural networks, extreme learning machines, and adaptive fuzzy neuron networks were often used. To conduct real-time forecasting of carbon pricing in Shenzhen, a hybrid of mixed data sampling regression and back propagation neural network was created, resulting in improved performance. The authors proposed a weather classification model based on generative adversarial networks and convolutional neural networks for day-ahead photovoltaic power forecasting, and it was discovered that weather classification is crucial in determining the most efficient photovoltaic power forecasting model.

A novel wave energy forecasting methodology based on artificial neural networks (ANN) has been suggested. Historical wave height and weather data from the wave measuring station are inputs to this framework. The present peak height of the wave energy is the output. On the basis of measurement data from China's east coast, the correctness of the forecasting system was confirmed. In, a comprehensive comparison of current renewable energy forecasting models was presented, demonstrating that each model had benefits and drawbacks. As a result, the articles in the fourth category propose how to combine several forecasting methods in order to maximize the benefits of each method individually. To combine forecasting accuracy with parameter stability, a hybrid forecasting system including a denoising approach, a multi-objective differential evolution algorithm, and a fuzzy time series method was created. To explore the large multi-step wind speed forecasting performance, a hybrid approach based on wavelet packet decomposition, Elman neural networks, and boosting algorithm was developed. Furthermore, wavelet decomposition and the least square support vector machine were utilized to greatly reduce the unpredictability and stochasticity in wind energy. The authors suggested a novel machine learning framework for forecasting major wave heights in Australia's eastern coastline region based on extreme learning machines and empirical model deconstruction. This framework may be seen as a useful decision-making tool, and it is essential for the development of dependable ocean energy converters [9]. The aforementioned techniques for renewable energy forecasting, on the other hand, often use shallow models as its learning principles. Neural networks having just one hidden layer or no hidden layer are known as shallow models. In the 1980s, shallow models were suggested to learn statistical principles from a large number of training samples in order to predict unknown occurrences. Back propagation algorithm, support vector machine, Boosting, and maximum entropy techniques are examples of shallow models. The training of shallow models, on the other hand, requires a great deal of knowledge and expertise. Furthermore, superficial model theoretical analysis is challenging. As a result, shallow models have significant practical constraints. To put it another way, shallow models have at least three major flaws: (1) Feature selection done by hand [10].

DISCUSSION ON FORECASTING OF RENEWABLE ENERGY

To manually choose features from renewable energy data, shallow learning algorithms need adequate previous knowledge of the issue area. Because the time-consuming feature selection procedure is heavily reliant on human experience and therefore inaccurate, shallow models are ineffective for detecting nonlinear features and high-level invariant patterns in renewable data.

(2) Limited capacity to generalize. Shallow models have been shown to excel in approximating smooth target functions. However, due of the noisy surroundings and chaotic nature of the weather system on Earth, renewable energy data is intermittent, stochastic, and highly variable, adding non-smooth features to the forecasting target function.

As a result, shallow models with limited generating capabilities may be ineffective in learning complicated patterns in renewable energy data. The number of samples. When the training dataset is tiny, shallow models perform effectively. The widespread deployment of environmental meters, remote sensors, and other related technologies, on the other hand, ushers us into the age of big data, with the training data trending exponentially higher. As a result, shallow models may experience network instability. Renewable energy forecasting has recently remained a hot topic in the literature, with many review articles being published. Forecasting PV power production approaches using time-series statistical, physical, and ensemble methodologies. The writers gave a comprehensive review of different methods for solar power forecasting over a relatively short time horizon to the readers. A survey on wind energy ramp forecasting, which is useful for achieving large-scale wind energy integration. Furthermore, the state of the art in wind and solar energy forecasting has been thoroughly examined from the viewpoints of cooperative and competitive ensemble techniques. The impact of solar and wind energy forecasts on electrical power and energy systems has been analyzed, as well as their operating costs and benefits. The authors examine the development of sea wave energy operation prediction in terms of energy balance, as well as statistically evaluate the dependency of wave and thermal energy by delving into the input function of wind energy.

Despite the fact that relevant research has exploded in recent years, the evaluation of renewable energy forecasting from the viewpoint of deep learning has yet to be addressed. As a result, the purpose of this article is to bridge that gap. The primary contribution of this article, in comparison to other research on comparable subjects, is to evaluate renewable energy forecasting literature from the perspective of deep learning-based techniques. We categorize the fundamental architecture of deep learning, as well as the related training processes, into four categories: deep belief networks, stacking auto-encoders, deep recurrent neural networks, and others. We look at how deep learning-based models may help in forecasting. Existing approaches are summarized and analyzed, such as data preprocessing and error post-correction procedures. We also talk about existing research projects, difficulties, and possible future research paths. The following is a breakdown of the paper's structure. A basic overview of deep learning-based renewable energy forecasting, as well as its categorization. A summary of the most often utilized deep architecture for deterministic and probabilistic renewable energy forecasting is provided. Several methods for improving accuracy are presented. We also discuss the statistically promising performance of deep learning-based techniques, as well as potential obstacles and future research areas. This section explains the fundamentals of deep learning, which is important for improving forecasting accuracy for renewable energy sources. In general, three major kinds of deep learning were widely used in the literature: stacking auto-encoder, deep belief network, and deep recurrent neural network. Forecasting models based on stacked extreme learning machines, deep reinforcement learning, and deep convolution neural networks have also been described. We'll now go over their fundamental architecture and the training processes that go with them.

Only the latent information in the hidden layer is used in the decoding process to recreate the inputs, suggesting that the latent variables already retain a lot of information from the input. As a result, the encoder and decoder's nonlinear transformation may be regarded as a sophisticated feature extractor capable of maintaining latent abstractions and invariant structures in input. After then, an SAE is created by discarding the decoder and stacking the encoders hierarchically. The first layer of an SAE is trained as an independent AE, with the input serving as the training

dataset. When the first auto-training encoder's process is over, the first AE's hidden layer and the second hidden layer are regarded as a new AE. The training procedure is same to that of the first AE. Multiple auto-encoders may be layered hierarchically in this manner by executing the encoding rule of each layer in a bottom-up order, and an SAE is formed as a result. Previous research has shown that SAE offers promising and stable performance for high-level feature abstractions and representations, which is useful for renewable energy forecasting. In recent years, several forecasting models based on SAE have been created. The term "deep recurrent neural network" comes from the term "recurrent neural network," which is a kind of artificial neural network in which nodes are connected to form a directed graph. It uses feedback connections to remember the brain states at earlier time steps to simulate the temporal dynamic behaviors seen in time series data.

Feed forward neural networks are a common RNN structure. RNNs may utilize neural internal states to analyze time series sequences of inputs, making them suitable for renewable energy forecasting. Deep RNN may be expressed in four distinct ways when compared to ordinary RNN. The first method is to deepen the input-to-hidden function to learn additional non-temporal structure from the inputs. This formulation, as opposed to the original inputs, tends to flatten the manifolds around which the data concentrates and untangle the underlying variation components. Because the connection between representation characteristics can be represented more simply, the deep input-to-hidden structure enables learning the temporal association between many time steps simpler. The second concept of deep RNN is to deepen the hidden-to-output function, which allows for more compact hidden states. The most significant advantage of this formulation is its great efficiency in summarizing the history of prior inputs, making real-time output prediction simpler. The third kind of deep RNN is the deep hidden-to-hidden transition. It adds a new data source to the previous inputs, which are represented by fixed-length concealed states. The hidden-to-hidden transition enables the hidden layers to quickly adjust to changing input patterns while maintaining a meaningful summary of previous data. The deep hidden-to-hidden transition's primary benefit is its universal approximation feature. The fourth kind of deep RNN is created by stacking several recurrent hidden layers on top of each other.

Each stacked layer is encouraged to function on a distinct timeframe by this arrangement. To put it another way, stacked RNN can deal with various time scales in a single input sequence. The four most common deep RNNs are shown in this diagram. For renewable energy forecasting, several deep RNN models have been suggested. Deep RNNs, on the other hand, may increase computing complexity, particularly when time series data has large tails. Adopting recurrent and convolutional operators for model building is one viable approach. Another option is to utilize bidirectional computations, which may account for the effects of both past and future situations. Additional stored states in a deep RNN may be controlled directly by the neural network. Furthermore, another neural network with time delays or feedback loops may be used to replace the recorded states. Long short-term memory networks and gated recurrent units rely on such regulated storages. They both have distinct temporal dynamic behavior and may alleviate the issues of bursting and disappearing gradients. As a result, for renewable energy forecasting, extended short-term memory and gated recurrent networks show promise. The substantial anomalies in terms of uncertainty and volatility add to the difficulty of renewable energy forecasting. The decomposition signal, according to the prior study, is made up of three parts: (1) A regular pattern used to characterize the inherited periodic signal from previous samples. Because of its predictability, it is a key component that can be precisely anticipated. (2) Uncertainty is a non-periodic component produced by external variables such as weather and climate. Because this component is influenced by random variables, it is difficult to anticipate. (3) Noise as a physical component that cannot be explained.

Because it is unexpected, this word is often overlooked and dismissed. Clearly, the examination of highly nonlinear, complicated relationships and correlations in data is required for predicting uncertainty, which may go beyond the conventional shallow learning paradigm. On the contrary, prior research have shown that deep learning algorithms have a tremendous approximation capacity to extract deep nonlinear characteristics in data, making deep learning ideal for renewable energy forecasting. The most significant advantage of deep learning architecture is that it can learn renewable energy data characteristics in a hierarchical manner. The neural network design learns the characteristics at various sharing levels at different layers. Typically, higher-level characteristics are learnt as a mixture of lower-level traits. Deep learning techniques, in general, may be utilized as feature extractors in an unsupervised way. The discovered characteristics are useful in renewable energy forecasting. All of the algorithms have been presented. Deep learning characteristics are not immediately applicable to renewable energy forecasts. To translate the nonlinear characteristics into the final forecasting findings in a supervised way, a regression procedure is needed. In the regression process, linear regression, nonlinear regression, and even neural networks may be utilized. By fitting a linear equation to the observed data, linear regression models the connections between the dependent variable and the explanatory factors. The linear equation depicts the relationship between the mean response and the explanatory factors. Nonlinear regression is a kind of regression analysis that uses statistics. The data are expressed as a nonlinear function whose parameters are determined by the explanatory factors in this approach.

CONCLUSION AND IMPLICATION

This article offers a thorough evaluation of current deep learning-based renewable energy forecasting models. A multi-layer perceptron with many hidden layers is what deep learning is. It combines low-level characteristics to create more abstract high-level features or characterizes attribute categories to learn about the input data's fundamental nature. Deep learning-based forecasting models are divided into five categories in this paper: DCNN, DRNN, DBN, SAE, and additional deep learning models. Each kind of forecasting model is described in depth. In addition, various data preparation and post processing methods are discussed in this article in order to enhance prediction accuracy. The article then goes on to provide a significant number of simulation results that demonstrate the feasibility and efficacy of deep learning-based forecasting models. Finally, we go through some of the difficulties that deep learning-based prediction models face, as well as some of the future research areas that might be pursued. This article's comparative analysis may aid renewable energy forecasting experts in determining which deep learning algorithm can help them improve their forecasting tools. This article fills in the gaps in order to explore the possibilities of deep learning in the context of renewable energy forecasting.

ABSTRACT

Soil erosion is a global issue that has a negative impact on agriculture. Soil erosion causes topsoil degradation, resulting in a decrease in soil productivity. The balance between soil farming and depletion is critical for long-term agricultural sustainability. Soil erosion is caused by a variety of causes, including deforestation, overgrazing, and the use of agrochemicals, among others. Crop production has been hampered by soil erosion, a shortage of water, and nutritional deficiencies. Various methods, such as vegetation, mulching, matting the soil, bunding, reducing irrigation, and jetties, may be used to minimize soil erosion and increase crop yield. This review article focuses on the effect of soil erosion on agriculture in this respect. Soil erosion has a negative impact on crop productivity in a variety of ways, including nutrient loss, soil depth, and water availability. Soil erosion may be avoided in the future by using appropriate land management techniques.

KEYWORDS:*Agriculture, Land, Organic Matter, Soil Erosion, Water, Wind.*

1. INTRODUCTION

By removing soil from land surfaces, erosion depletes the viability of all natural habitats, including agricultural, forest, and pasture ecosystems. Soil erosion, water shortages, climate change caused by carbon pollution, eutrophication of fresh water and underwater shorelines, and habitat loss are among the world's most pressing environmental problems. According to reports, almost 66 percent of the world's population is malnourished, the highest number of malnourished individuals ever recorded. More food will be required when the world's population surpasses seven billion people, with a predicted 9.3 billion by 2050. Consider that over 99.7% of human

food (calories) is processed on the land, while less than 0.3 percent of marine and aquatic food (calorie) is. For all agricultural soils, productivity and quality are critical to the preservation and growth of global food supply. For many years, human-induced soil degradation and the consequent damage to all agricultural land has resulted in a reduction in the productivity of the remaining land, which has been somewhat countered by nitrogen and phosphate fertilizers, culminating in the abandonment of productive agricultural soil. Soil erosion results in the loss of farmland, which necessitates the processing and application of nitrogen and phosphate enzymes to new cropland, as well as new cultivations from forest and pastureland. Soil erosion also reduces the number of important plant, animal, and soil microbes [1], [2].

Soil degradation is agriculture's biggest foe, posing a significant environmental threat to long-term sustainability and development, as well as the impacts of the climate and food security crises. This is especially true in places where there are major issues, such as watersheds in Indonesia, India, the Philippines, and other countries. By using sustainable land management to prevent soil erosion, these places may solve a variety of issues. Soil depletion may include things like erosion, compacted soil, low organic matter, a lack of soil structure, inadequate internal drainage, salinization, and acidity issues. Other kinds of soil loss also result in soil erosion, but this is more severe in them. Soil deterioration is a common phenomenon in nature. Soil erosion is caused by water and wind, and each year they contribute to a considerable quantity of soil depletion throughout the world. Soil erosion may be a gradual, undetected process or it can happen quickly, resulting in significant topsoil loss. Reduced agricultural production capacity, lower surface water productivity, and deteriorated irrigation networks may all contribute to land depletion. The effect of soil erosion on agriculture and the many variables that induce soil erosion were addressed in this review article. How do these variables contribute to soil erosion, which has a negative impact on agriculture [3], [4].

2. SOIL EROSION AND ITS CAUSES

Soil erosion is a gradual process in which soil particles are separated by water or wind, allowing the soil to degrade. As a consequence of deforestation and surface runoff, soil erosion and poor water quality have become significant problems all over the globe. The situation may deteriorate to the point when the land cannot be cultivated and must be abandoned. Many agricultural civilizations have perished as a result of mismanagement of land and natural resources, and the history of such civilizations serves as a stark warning to preserve our natural resources. Soil erosion has the potential to harm agriculture by reducing crop production and quality. In a time when the world's population is increasing, the agricultural industry is under pressure to produce enough food to support our modern society. On the other side, climate change and deforestation cause soil erosion, which reduces agricultural output across the globe [5], [6].

2.1. Soil Erosion Causes:

The only way to prevent erosion is to have a permanent surface covering on the soil surface, such as trees, pastures, or prairies. In contrast to early forest soils, soils in grassy fields and agricultural regions are less capable of sustaining and are more susceptible to erosion. There are more floods in these soil regions because their water absorption capacity is decreased (and their commercial, social and environmental effects). Soil erosion is caused by a variety of causes. The four main causes are shown in Figure 1.

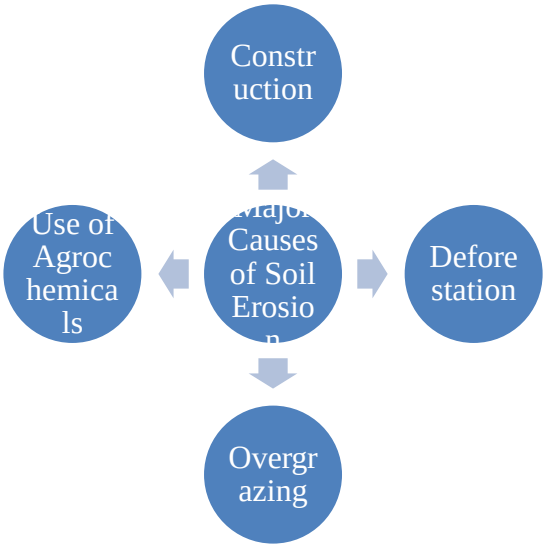

Figure 1: Schematically illustrates the major causes of soil erosion

2.1.1. Deforestation:

The population is increasing demand for goods like as coffee, soybeans, palm oil, and wheat, which is clearing space for cultivation. Unfortunately, it increases the risk of native trees eroding and being replaced by new trees that do not always cling to the soil. Agriculture would be jeopardized if topsoil (the soil's most nutrient-dense layer) was eroded over time.

2.1.2. Overgrazing:

Overgrazing is caused by continuous bovine growth. Animals are flattened and compressed because plants have little time to recover. Topsoil sediments are taken away during this process. On the other hand, the remaining soils may lose their penetration capability, resulting in additional climatic water loss.

2.4. Agrochemical Application:

Pesticide and fertilizer chemists are a popular method for farmers to boost their profits on (typically monocultural) crops. Overuse of phosphoric chemicals, on the other hand, promotes the growth of harmful bacteria, leading in an imbalance of soil moisture in the microorganism. If the soil deteriorates, the risk of floods rises, and sediments wash away in rivers and adjacent regions (due to wind and water behavior), contaminating the local living environment. Farmers utilize tillage techniques to prepare crops by adding chemicals and fertilizers, as well as soil leveling and invasive crop removal to grow them. This is not only correct, but also very important. Because tillage changes the soil's composition, it accelerates soil erosion and surface runoff.

2.5. Recreational and construction activities:

Buildings and roads that prevent water from flowing freely contribute to surface deterioration. Rather of speeding up deforestation, it is flooding adjacent areas. Furthermore, motor sports such as motocross harm the environment, alter it (albeit to a lesser extent than other factors), and degrade soil.

3. IMPACT OF SOIL EROSION ON AGRICULTURE

Soil erosion is a slow process in which the soil is eroded and separated by water or wind, causing the soil to degrade. Erosion and surface runoff have caused substantial soil loss and poor water quality throughout the globe. The situation may deteriorate to the point when the land cannot be cultivated and must be abandoned. Because of mismanagement of land and natural resources,

many pastoral cultures have perished, and the history of such civilizations serves as a warning that our natural resources must be preserved. Erosion is a significant issue that affects both productive agriculture and water quality. To enhance water and soil quality, sediment control must be a component of every soil management strategy. Topsoil eroded by wind or water may be carried via streams and other rivers. Land erosion produces sediments, which is mostly produced by sheets and rill erosion in highland areas, and to a lesser extent by cyclical erosion of slopes and drainages [7], [8].

Crop yields are decreased as a consequence of soil erosion. In order to decrease water infiltration and storage, soil erosion enhances water flow. Water flow is increased by soil erosion. Furthermore, the erosion process removes organic matter and vital plant nutrients from the soil. These enhancements not only decrease vegetative production, but they also reduce the presence of important biota and soil biodiversity. Because these factors interact, it's almost difficult to separate their distinct impacts. These elements are explored more below:

3.1. Availability of Water:

Water is a major productivity limitation in all terrestrial environments since all plants needs enormous amounts of water to grow and produce fruits. For example, in a three-month growing season, a hectare of maize would use approximately seven million liters of water and lose another two million liters to the soil. Water drainage is very important because precipitation drains the surface, reducing water penetration into the soil.

4.2. Nutrient Depletion:

Plant nutrients such as nitrogen, phosphorus, potassium, and calcium are carried by eroded soil. The leftover soil usually maintains three times as many nutrients per unit weight as the deteriorated soil. Fertile topsoil contains 1 to 6 kilogram of nitrogen, 1 to 3 kg of phosphorus, and 2 to 30 kg of potassium per ton, whereas eroded topsoil has 0.1 to 0.5 kg of nitrogen per ton. A high amount of fertilizer is also used to compensate for nutritional deficiencies in crop production. Commercial fertilizer and/or cow manure may replenish the nutrient base when the soil base is approximately 300 mm deep and only 10-20 tons of ground per acre per year is lost. However, implementing a replacement approach is costly for both farmers and the economy, and most impoverished farmers cannot buy fertilizer. Not only are fossil-fuel fertilizers reliant on fertilizers, but they may also harm human health by polluting soil, water, and air.

3.3. Organic Matter in the Soil:

The amount of organic matter in rich soils is about 100 tons per hectare (4 percent to 5 percent of total topsoil weight). 95 percent of nitrogen and 25 to 50 percent of phosphorus are found in organic matter in the soil. Erosion significantly decreases organic soil since most organic soils reside as rotting leaves and stems near to the earth's surface. Wind and water erosion remove fine organic particles from the soil, leaving bigger soil and rock particles. Several studies have shown that soil that has been dissolved by water or wind is 1.3 to 5 times richer than soil that has been left in organic materials. For example, decreasing organic soil content from 0.9 percent to 1.4 percent (assuming organic soil content is 4 percent to 5 percent) reduced grain crop production capacity by 50%.

Soil organic matter is a significant resource because it helps in the formation of soil aggregates, which improves soil porosity. As a consequence of the enhanced soil structure, water penetration improves and the soil's total productivity rises. Organic matter also aids in the exchange of caution, the development of plant roots, and the proliferation of soil microbes. The ecosystem's productivity declines when the organic matter layer is depleted, as measured by plant biomass, due to deteriorated soil composition and nutrient losses. In addition to low yields, overall biomass and biodiversity of biota have decreased significantly in these environments.

3.4. Depth of Soil:

Growing plants need soil that is deep enough for their roots to reach. Various soil biota, such as earthworms, need a certain soil depth. This implies that when erosion lowers soil depth from 30 cm to less than 1 cm for shallow soils, root space will be reduced and plants would be stunted.

4. PREVENTION OF SOIL EROSION

Soil erosion is a concern not just because it affects plant development, but also because it has an impact on water quality. Soil is an important natural resource that, among other things, nourishes and encourages plant development. When soil is left uncovered and exposed, it will be eroded by wind and water. There are a few methods that may be used to avoid soil erosion [9], [10].

4.1. Vegetation:

The simplest and most natural method to prevent soil erosion is to plant plants. Because bare-earth soil erosion is more severe, the soil must be maintained covered by planting and growing grass. Water is slowed by the grass, which keeps it from coming into direct touch with the surface. Plants produce root systems that aid in soil stabilization and erosion prevention. Plants shield rain and reduce the impact of the drop on the soil via their leaves, preventing the soil from being split apart.

5.2. Mulch Application:

Mulches are another method to keep soil from eroding. Mulch on the soil surface aids in the gradual absorption of water while also protecting the soil from rain and correcting pH levels. Mulching is made from dead leaves and broken wood that fall to the ground and cover the soil. Mulching protects trees and plants from the elements. Mulching allows water to slowly reach the land, reducing the impact of heavy rain or irrigation. Mulches help to keep the soil from becoming acidic and to keep weeds at bay. Mulches produced from organic materials decompose over time, improving soil structure and fertility.

4.3. Soil Matting:

Matting is used to add biodegredients to the soil, such as mulch, straw, cacao, and wood chips. These are kept in place with the use of biodegradable coconut netting. The proper method for burying a biodegradable tapestry. The matting material decomposes or slows down decomposition, eventually becoming a soil fertilizer.

4.4. Construction of Retaining Walls:

It's conceivable that sloping terrain may revert to its previous state before stabilizing. The slope's bottom supporting wall will keep the dirt from creeping and delaying the collapse. The retaining wall frequently prevents water leaks. More erosion is caused by runoff water, which may be mitigated by a stone or concrete wall.

4.5. Integrate Hillside Farming with Contour Farming:

On sloping terrain, soil erosion is more frequent. On the steepest slopes, cultivating is almost impossible. Divide the hill into terraces that wrap around the slope to prevent soil erosion. To prevent soil erosion, the dirt should be placed evenly down the slope. Contour agriculture acts as a buffer, catching and retaining rainwater for increased infiltration and more consistent water supply.

4.6. Bunding:

A bund is an erosion-prevention method that involves placing a barrier on the surface rush to restrict water flow. It aids in the management of soil depletion caused by runoff buildup in the watershed. The contour channel may be excavated in the same manner on both sides of the river. Contour linkages are formed in low-precipitation regions with porous soils.

4.7. Reduce the amount of water you use:

Soil erosion may occur when a garden or field is overwatered. Whenever possible, use less water. The safest approach is to use a drip irrigation system. A drip system provides just a little amount of water at a time and no water runs over the surface to maintain top soil.

4.8. Avoid Compaction of the Soil:

The earth is compacted into a thick layer by people, animals, and machinery all pressing down on it. As a consequence of compaction, the spacing between soil particles shrinks. Water and oxygen have a difficult time reaching the soil as a consequence. As a consequence, rather of stomping the ground, a moving path made of paving stones should be constructed.

4.9. Creation of Windbreakers:

Evergreen trees are planted around gardens or farms in this technique to prevent the soil from blowing away. Windbreakers protect plants from wind damage while also increasing their efficiency and output. Humidity is considerably higher in a crop that is sheltered from the wind.

4.10. Groins:

Sand is carried down the beach by longshore drift, and groins are man-made structures designed to collect it. Longshore drift is a mode of transportation. It refers to the movement of eroded debris along a shoreline. Groins are long, walk-like structures built on beaches that extend into the water perpendicular to the coastline. They prevent longshore currents from flowing. The long beach current loses pace as it reaches its groin, which consists of sand dumps and silt on the current side of the wall. While the sand on the upstream wall is being caught, the waves are picking up sand and gravel on the downstream side.

4.11. Jetties:

People rushing around the sides of the entry generate jetties, which are barriers. The goal of the jetty construction is to keep the Inlet open forever and prevent it from moving. This approach necessitates the construction of a lengthy system that runs parallel to the sea. They are usually made of stone, cement, steel, or wood and are used to keep sand out of a ship's passage. Beach should be spread over the sand on the current side of the jetties to reduce erosion even further. On the downstream side of the jetties, erosion continues.

4.12. Breakwaters:

Breakwaters are made up of large rock piles that run parallel to the beach. Breakwaters are usually utilized to cool the waters in ports and manmade marinas. It serves as a wave barrier, allowing the beach to expand while preventing erosion. As waves slam against the barrier, they discharge their sediment burden. On the other hand, any portion of the coast that isn't covered by the breakwater starts to deteriorate.

5. DISCUSSION

Soil erosion occurs when soil particles loosen or wash away in valleys, oceans, rivers, streams, or distant regions. Agriculture and deforestation, for example, have worsened the problem. Soil erosion is a constant process that may happen slowly or quickly. It causes, among other things, a gradual loss of topsoil, ecological degradation, and soil collapse. Increased rainfall rates are the primary cause of soil erosion. Raindrops scatter the dirt, which is carried away into nearby

streams and rivers. Soil depletion is common in regions with heavy and regular precipitation. During floods, the rushing water erodes a lot of soil, causing potholes, rock-cut tanks, and other problems.

As the most productive portion of the soil profile, soil erosion depletes the top soil for agriculture. In the lack of top soil, yields are decreased and production expenses are increased. Erosion may cause erosion because high soil is lost, making paddock expansion harder. Erosion in croplands leads in exposure to water and nutrients, poor physical and chemical characteristics of the subsoil, higher ripples, water and other nutrients for crop development, depletion of freshly planted crops, and silt deposition in lowland regions. Erosions may also lead to a decrease in the amount of water and nutrients contained in the soil.

6. CONCLUSION

Soil erosion is a natural occurrence that may occur on any kind of terrain. Soil erosion is a frequent physical force in agriculture caused by water and wind, and is related to agricultural operations such as tillage and wearing down a top-soil region. Soil separation, redistribution, and absorption are three distinct processes involved in erosion, whether caused by water, wind, or the preparing of ground for growing crops. Top soil, which is high in organic matter, fertility, and soil life, is either moved on-site to grow over time or transported "off-site" to fill drainage ditches. Soil erosion lowers agricultural production and pollutes rivers, lakes, and streams in the area. Soil erosion may be a gradual, undetected process or it can happen quickly, resulting in significant topsoil loss. Other severe soil depletion characteristics that may speed up the erosion process include soil compaction, low organic matter, and lack of soil composition, poor internal drainage, salinization, and acidic conditions. It is suggested that appropriate land management methods be used to avoid soil erosion by taking into account all problems connected to soil erosion. It is necessary to investigate how small farmers may become more aware of soil erosion and how to avoid it.

UZBEKISTAN

ABSTRACT

The theory of structuralism introduced the linguistics of Uzbek at the end of the last century by following the relationship of linguistics and the problematic of the theme chosen in this article it is about the analysis of the binary construction in the discourse that allows to gather among all these elements phrases in the syntaxes of the French-Uzbek language.

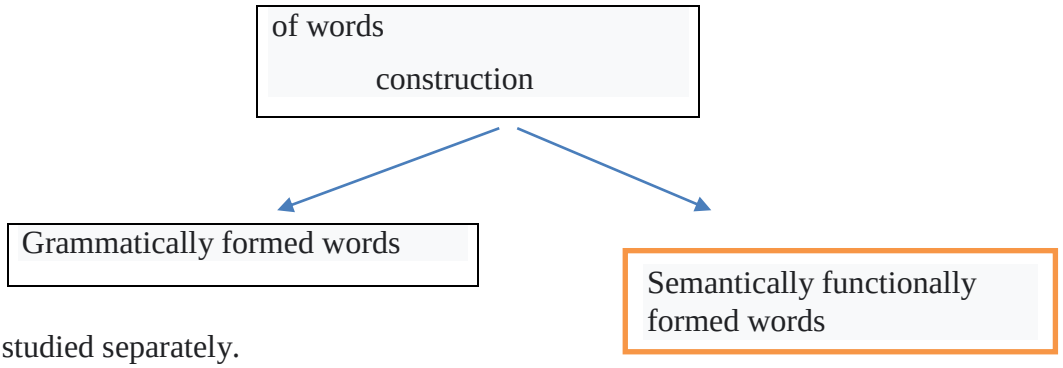
KEYWORDS: *System-Structural Linguistics, Modal, Exclamation, Affirmation-Denial, Suggestion-Address, Binary Construction, Component, Boundary Comparative Linguistics, Opposition, Relative.*

INTRODUCTION

In the latest research of Uzbek linguistics, the doctrine of system-structural linguistics created in Europe and its theorists (V. Humboldt, F. de Saussure, S. Balli, G. Guillaume, K. German, J. Dubois, R. Jacobson, A. Tenyer et al.). It aims not only to emphasize the advantages of the methods of system-structural linguistic analysis, but also to bring advanced linguistic theoretical views into the Uzbek language and use them in the most effective and comparative-typological aspects. It is no coincidence that Humboldt said almost two centuries ago, "Every language has its own system, and a linguist must study it." In recent years, the methodology of dialectical laws of linguistic and speech phenomena has undergone a deeper analysis of problematic issues at all levels of linguistics. A real "Turkish delicacy" is beginning to be felt in all parts of the Uzbek language, and it is thanks to our independence that serious efforts have been made to free it from "excessive grammatical burdens." Indeed, language and speech are very complex in their content and the relationship between them. This doctrine is also important for the work we are studying.

MAIN PART

In the same direction in Uzbek

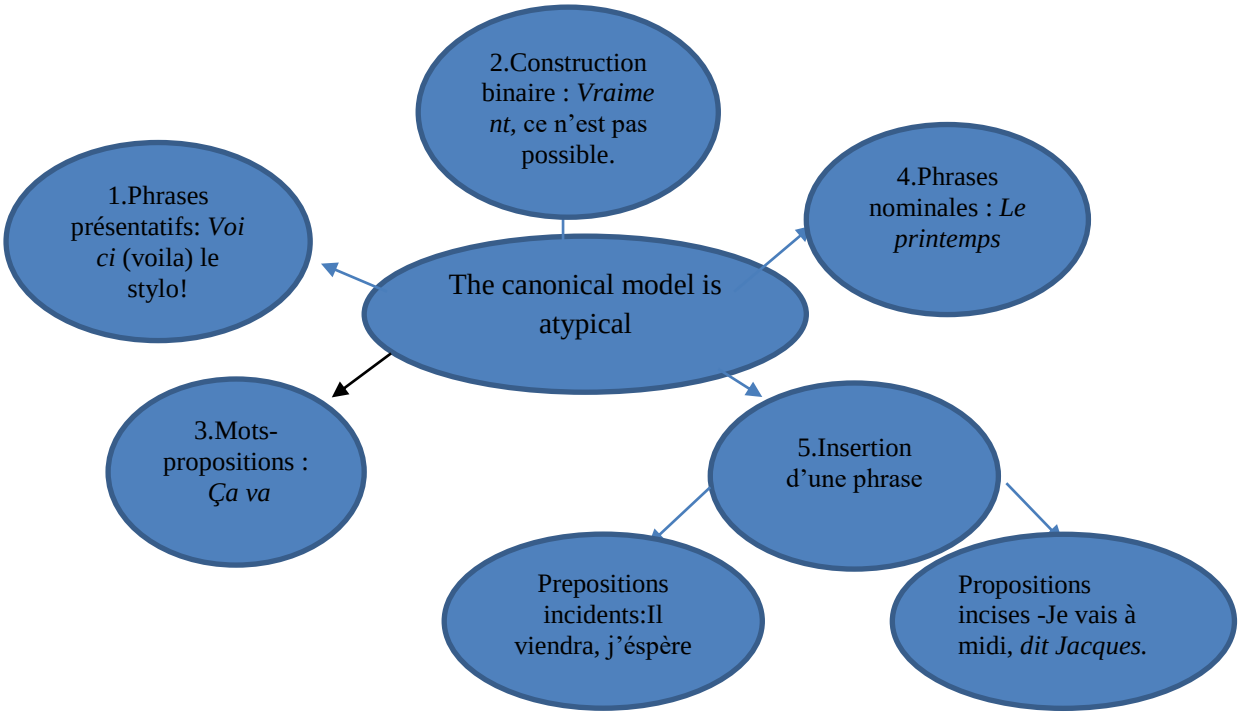


were studied separately.

In the latest scientific literature in French: 1. Typical 2. Atypical sentences are distinguished from each other.

The canonical model is used as an atypical phenomenon for the construction of speech in modern French literary language, and it can be contrasted with typical sentences.

The canonical model is an atypical statement:



Atypical sentences in Uzbek can be compared with ssemantically, functionally formed words. In the syntactic framework, the features of ssemantically functionally formed words are limited, such as the fact that they do not require a grammatical form, in other words, the inability to semantically communicate, are not considered part of speech and are not connected with parts of speech. In French, however, these signs are not fully justified. Recent studies have shown that constructive, nominative, author's, introductory, and adverbial sentences, which do not occur in SFSHSGs, have a canonical model (separate construction). . Due to the nature of the dichotomy

of language and speech, the minimum grammatical pattern of speech differs sharply in French and Uzbek. The same situation is observed in the formal structure of sentences (passive subordonnée form, building constructions, les énonces à un seul terme, l'emphase, mots-propositions in separate sentence types).

Semantically and functionally formed sentences usually consist of modal, adverbial, affirmative, negative, and adverbial words. These are given in the symbol (WP) as opposed to grammatically formed words, which are (WPm) stereotypes.

Indeed, there are also lexical units that have the ability to be spoken between French lexicon and syntax. Their lexical-semantic and syntactic features have not yet been scientifically determined. However, we seek to provide scientific information on the lexical-semantic and functional properties of binary constructed sentences, acknowledging that the ontological features of the semantically functionally formed words mentioned above are also reflected in the canonical model of atypical sentences.

French linguists thought about the problems of binary opposition in the first half of the twentieth century. For example, Anre Martine, a professor at theSorbonne University and one of the founders of functional linguistics, in his work on lexicology, La linguistique synchronique, provided interesting evidence for the emergence of binary opposition in relation to process and object.

For example, the binary contradiction between the expression of the meaning of the table (table) in the form of "table" and the expression [tabl] is reflected in the linguistic conflict. The scientist's conclusion is that binary opposition is manifested in the relation of "sign and determinant" (le signifié et le signifiant). That is, this relationship is important for the observation of lexical units in the speech process.Although binary construction is essentially inextricably linked to binary opposition; it differs markedly in some respects. What is the difference?

1. In the syntactic construction of lexical units, that is, in the acquisition of a functional essence.

2. A lexical unit expresses a lexical meaning while retaining its essence in binary opposition. In binary construction, syntactic construction is more important than lexical meaning.

3. In the form structure of syntactic construction. A lexical unit or lexical device in a speech function is essentially specific to a particular type of speech.

For example, the primary function of a group of horses in a binary construction is explained by the fact that they are nominal. Its expression by prepositional determinants is related to the incomplete sentence. When we say formal structure of syntactic construction, we mean what kind of sentence it belongs to. In the textbooks of Grammaire métodique du français (2) by Martin Regel, Jean-Christophe, Relat and Rene Reyol, the term "binary construction" is used as a lexically and syntactically separate "component" (relative sense). We have to admit that. (The term "binary construction" or "binary construction sentence" is not listed as a separate sentence type). In it, the terms "binary opposition" and "binary construction" have two different meanings: 1) lexical semantic; 2) studied in the syntactic and stylistic plan. A binary structure with a distinct linguistic structure is an important speech phenomenon for SFSHSG (semantically-functionally formed simple sentences). The study of these is important for comparative typology and theoretical gammatics.

An analysis of the French language shows that many sentences can consist of two relatively independent parts. Such passages create opposition in the speech. But they do not take into account the logical judgment inherent in the speech. On the contrary, the content of the first part of the opposition is interpreted in relation to the content of the second part, and the connection

with this content is equivalent to a complete idea. The main reason for this is that the simple statement is in binary opposition. In other words, simple sentences from French form relative (independent) two-component sentences when they switch to binary opposition. In them, even when the components appear to be two, the logical judgment is one and loses the cross-sectional area.

Binary opposition of a simple sentence	**The normative structure of a simple sentence**
Belles, les filles!	*Les filles sont belles.*
Magnifique, ce tableau !	*Ce tableau est magnifique.*
Drole, cette histoire !	*Cette histoire est drole.*
Delicieux, ce plat !	*Ce plat est delicieux.*
Dangeureux, ce pont.	*Ce pont est dengeureux.*
Capricieux, cet homme.	*Cet homme est capricieux.*
Claire, votre explication !	*Votre explication est claire.*
Heureux, les pauvres !	*Les pauvres sont heureux.*
Artificiel, son rire.	*Son rire était artificiel.*
Beau, le temps !	*Le temps est beau.*
Autobiographique, le roman.	*Le roman est autobiographique.*
Aveugle, cette femme.	*Cette femme est aveugle.*
Aviateur, son fils.	*Son fills est aviateur.*
Jaloux, mon mari.	*Mon mari est jaloux.*
Pardonnable, ce garçon.	*Ce garçon est pardonnable.*
Nombreuse, sa famille.	*Sa famille est nomreuse.*
Inutilisable, sa voiture.	*Sa voiture est inutilisable.*
Unique, sa fillette !	*Sa fillette est unique.*
Cacochyme, ce malade.	*Ce malade est cacochyme.*
Faible, ce boxeur.	*Ce boxeur est faible.*
Fantastiques, tes idées !	*Tes idées sont fantastiques.*
Flegmatique, cette personne !	*Cette personne est flegmatique.*
Compréhensible, cette règle !	*Cette règle est compréhensible.*
Rapide, ce moto!	*Ce moto marche rapidement.*
Prudent, ce chauffeur.	*Ce chauffeur conduit prudemment.*
Chaleureux, l'été!	*L'été est chaleureux.*
60 degrès,la température!	*La température montre 60 degrès.*
Jeune, l'avocat!	*L'avocat est jeune.*
Beau,ce paysage!	*Ce paysage est beau.*
Ancienne, cette boucle d'oreille!	*Cette boucle d'oreille est ancienne.*
Laborieux, ces pauvres !	*Ces pauvres sont laborieux.*
Paresseux, Luc !	*Luc est paresseux.*
Charmantes,ces dames !	*Ces dames sont charmantes.*
Si tendre, son amour !	*Son amour est si tendre.*
Discutable,ce theme !	*Ce theme est discutable.*
Voyante, M.me Leblanc !	*M.me Leblanc est voyante.*
Curieux, votre fils !	*Votre fils est curieux.*

Avare,ce monsieur !	*Ce monsieur est avare.*
Gaté, cet enfant !	*Cet enfant est gaté*

CONCLUSION

It seems that in the binary opposition of a simple sentence there are no intermediate elements of syntactic connection, but the parts are known and interconnected by a certain pause (tone). French linguists Martin Regel, Jean-Christophe, Pellat, and Rene Reul have commented on binary constructions. It should be noted, however, that it is confused with other types of simple sentences, such as incomplete sentences and types of words. In our opinion, binary constructions can be considered as a separate form of a simple sentence, and the study of its boundaries and forms is also important for comparative linguistics.

TESOL AND TETE INTERNATIONAL PROGRAMS RECOMMENDATIONS FOR TRAINING AND ORGANIZING SUCCESSFUL LESSONS

Kaharova Madina Bakhodirovna*

*Lecturer,
Department Translation Studies and Language Education,
Bukhara State University, UZBEKISTAN

ABSTRACT

The article deals with the training NAD organizing successful lessons on TESOL and TETE programs. The head and instructors taught Uzbek core teachers how to train teachers to be more professional in their teaching field. The root theories of SLA teaching, strategies of teaching a foreign language, innovative methodology and many interactive activities teaching workshops had been organized by TESOL and TETE training groups that was supported by Ministry of Public Education and American Councils. According to these seminars, Uzbek teachers practice their new gained methodological skills both during the program and after it, in their practicum phase.

KEYWORDS:*TESOL, TETE, SLA, Ice Breaker, Warm Ups, Transaction, Assessment, Autonomy, Reflecting, Scaffolding.*

INTRODUCTION

In 2021, TESOL's conclusive program sessions were held in Tashkent. The head and instructors taught Uzbek core teachers how to train teachers to be more professional in their teaching field. The root theories of SLA teaching, strategies of teaching a foreign language, innovative methodology and many interactive activities teaching workshops had been organized by TESOL and TETE training groups that was supported by Ministry of Public Education and American Councils. According to these seminars, Uzbek teachers practice their new gained methodological skills both during the program and after it, in their practicum phase. Several main points of those trainings will be described and analyzed in this article.

MAIN PART 1

Ice Breakers and Warm Ups — According to TESOL group, teachers must organize some ice-breakers or warm up activities before starting their lessons. These activities help students to overcome their inhibition, energize them, helps to build good rapport and to build nice transaction from start to body of the lesson. Some offered ice-breakers were:

a)Great Wind Blows – Teacher first clearly explains the task and models it. Then starts to ask some certain question that he/she prepared beforehand. Students or trainees will answer by waving their hands not "me" or "I did". It helps to build great students- teacher rapport and break all ices and smoothly lead to active class engagement. Questions' difficulty rate depends on the students or trainees level and purpose. If its ordinary class of 5th grade they can be "Who has a red scarf", "Who has been abroad?" "Who has a pet". If they are professional teachers that have been training, trainer can ask:" Who has IELTS score?" "Who participated in sport competitions?" "Who taught more than 5 years?" and so forth. Each time, instead of answer, participants wave their hands and make sound of the great wind. In result, very cheerful, smiling, safe, comfy and relaxing language learning atmosphere will appear.

b)Ball Throw - Teacher brings a ball. All students make a circle. One student throws a ball to other students and say "My name is Olim" Second will say "Thank you Olim my name is Noza", so other will continue in this way getting know each other. Teacher throws two more balls later, which makes these rotations more difficult. The rule of a game is students should remember from whom they get a ball and to whom they throw the names of those students too. Then additional questions will appear like "Who you want to be in the future?"

2. Assessing And Assessment Tools - Assessing students is one of the burning point of teaching and confusing part for many teachers. Right assessment tool both motivates student and makes easier teacher's load. Detail-oriented assessment tools work well to evaluate. Teachers can themselves decide, choose even develop according to TESOL and TETE groups. As tasks vary, assessment tools also fit to certain tasks but not all. Some may be: tables, rubric, checklist, survey, needs analysis tool, polls, foldable, anecdotal record, benchmark, conference, end-of year test, observation, oral reading assessment, peer assessment, performance assessment, reading history, rubric, self-assessment, standardized test, writing assessment. All of those notions will be in detail described in the next article.

3. **Learner AutonomyAnd Differentiated Instructions**- This theory states that teacher must give autonomy to the students in process of studying. Also in wide terms, it4means to give a choice to students or trainees. Effective trainer or teacher should be able always give several choice tasks to accomplish because not only tastes and preferences, but also abilities differ. There was an exam scene in manual, depicting many animals including monkey, fish, bird, elephant, snake lining up in front of examiner and a tree. Examiner was asking to climb a tree. It is clear that fish or elephant can't climb on it and fail. A bird will just fly and lands on it which is cheating. Monkey can perfectly do task and enjoy it. So, this picture reminds to teachers that students also may have distinct abilities. Taking into account this, teachers or trainers should offer a variety of activities to students to choose. For example, for finals not only translating the text but also writing essay, speak on topic, make power point presentation, tape a video, write a song, write voice on recorder and so forth.

4.Reflecting - As it was stressed on this procedure and term, TETE group urged many times to use reflective skills for being professional teachers. Each lesson, after each large project we wrote reflection thoughts to this group as an assigned essential part of trainings. As this group believes, reflections make teacher work on their professional skills, get experts in their field. Reflections let teachers know where are their weaknesses and strengths, where they should stress and develop in their lessons and where they should slow down or scaffold language delivery. While reflecting and observing other's reflections, teachers can start approach to their teaching skills and critical thinking skills differently, start being multifaceted teachers. Additional to this groups suggestions, I can offer to keep a diary of reflections, tape to videos some lessons that teachers think that it was their turning point in their teaching field, enrich and edit them, issue and share with other teachers as manuals. It not only improves writing and critical thinking, but helps efficient ideas to get spread.

5. Scaffolding – This term and teaching technique is used to describe the word giving more detailed help, instruct, explain, simplify, direct, facilitate. If there is misunderstanding, teacher explains it in simplified version, models it, gives clear examples. If context is difficult and long – shortens it, paraphrases, defines new words. If textbook is authentic and hard to 'digest' – helps to understand it. Tries to give big picture of a task or instruction, or recites core meaning of an extract. Or pairs students with more intelligent one, so the first can get a help. Or distributes a dictionary, so students can dive into task himself/herself.

6. Cascading – Trainers of TESOL use this term to identify the actions of teaching and training teachers to use newly acquired methodological and innovative teaching ideas to other peer teachers so they can deliver to others. Like a pyramid, core teachers will be able to work on certain about of teachers' training of ESL/EFL teaching, while those teachers can design and deliver training programs to other more amount of teachers. So, training process gets vast and widen its horizons.

7. Quizlet - on the website quizlet.com teacher enters appropriate text and the website tools aids the teacher to make up ready quizzes, polls and questionnaire to check each module or unit that students have been studying.

8. Active Words List – Teacher provides active new vocabulary or terminology will be used in teaching the class to students beforehand both in hard and electronic copy. Students will read them and do Quizlet tests to check themselves and consolidate the new knowledge that are going to gain.

9. **Attention Getters, Energizers, TPR** – These international teacher training program trainers also proposed to use attention getters to grab student's attention to announce, give instruction or monitor, such as: clapping, using flash, whistling, showing flag, raising hands, saying one word "Teacher" students will say back "students" or teacher says "wonderful" students say "stars" back to show their response attention. These attention getters may be established as routines which saves time, motivates. Also energizers were offered to use to give students some relaxing time and make tactile-dynamic students engaged into lesson. Such as: **Tiger, bear and hunter.** In two groups students will get lined up. Students in groups come into agreement show (mime, act, play a role of) one of those animals or person above, another group shows another one. There is a rule of energizer: the tiger beats the hunter because it eats a person, the hunter beats the bird because he has an arm, the bird wins the tiger because it can fly. So, turn by turn they show these roles in gestures like by showing a paw or flying sign or by an arrow sign. After playing some, the winner group will be clarified. A lot of fun, joy, cheerful relaxed learning atmosphere will appear and teacher and students with each other can build good rapport. TPR means total physical response where students learn new words, teacher acts or students act and other will imitate or find out what has been shown.

10. Action Plans - TETE program trainers has offered to English teachers totally new idea of using action plans to train teachers. According to it, timetable will be developed. Timetable will have: a) workshop title, topics b) objectives c) learning/training activities d) assessment parts. All parts will be thoroughly planned and filled by trainer. Each activity, its objective, using methods, assessing tools, time management, training mode will be described in action plan. It looks like curriculum. Doing so, teachers will equip themselves will detailed document. Goals and objectives for each lesson and activities will enable trainer and trainees know strengths and weaknesses, gaps, needs and so forth. It also resembles to needs analysis.

11. Building Routines – If teacher helps to build routines or establish group norms in English learning classes much time will be saved, noise reduced, effective lesson management will occur. Teacher either can state them each lesson and ask students learn them by heart, or make

some colorful poster and stick them on walls, decorate with them English room so students can learn them themselves, watch them in free time for pictures and learn norms.

12. Exit Ticket - TETE trainings teach to check comprehension students, monitor them, give clear instructions and model instructions to make them lesson content as clear as possible. Mainly to consolidate learnings teachers asks to answer the question: What two things I learned from today's lesson? And take notes in their notebooks or in the separate sheet of papers that teacher distributed. When the bell rings for break, students will submit answers as exit tickets and teacher will achieve total student attention or engagement during lesson. Responsibility of filling exit tickets will make students learn at least two things during the lesson. Teacher connects their learning with ticket. Tickets can start with: I know…, I learned…, I wish …, I need…

ABSTRACT

Data warehousing has become the most essential tool for every industry's decision makers. Essentially, data warehousing is the process of gathering and storing historical data in a single repository, referred to as a data warehouse, and then utilizing that warehouse to provide analytical findings. Being a helping hand for top-level professionals, it is always in the spotlight of the database business, presenting new difficulties on a daily basis. We provide a critical evaluation of data warehousing, as well as various types of topologies and data modeling for data warehouses, in this article. In terms of front end and backend technologies, we discussed some of the current data warehousing tools and methods available. We looked at other difficulties and concerns, as well as some of the study topics in data warehousing.

KEYWORDS: Conceptual Data, Data Warehouse, Data Model Quality Metrics, Online Analytical Processing.

INTRODUCTION

A data warehouse is a storage location for historical data from many sources. Rather than transaction processing, it is intended for inquiry and analysis. Furthermore, the data warehousing concept encompasses the tools and techniques available for data extraction, transformation, and loading, as well as an OLAP engine, client analysis tools, and other applications used to manage and process data in order to provide decision support to knowledge workers or decision makers. "A Data warehouse is a subject-oriented, integrated, time-variant, and non-volatile collection of data in support of management's decision-making process," says William Hinson, a well-known Data warehouse architect [1]. This description distinguishes the Data warehouse from other data repository systems such as relational database, transaction, and file systems.

In any business, a Data Warehouse is a step toward creating a computer system capable of analyzing patterns and assisting in crucial decision making. From past data, we may sometimes

find extremely fascinating and helpful trends that we might utilize for future planning. The traditional operational databases were designed to aid in the organization's clerical activities, while data warehouse and OLAP technologies are designed to aid decision makers (e.g., managers, analysts, etc.). As a result, new problems in the fields of data warehousing and OLAP emerge on a daily basis to meet the needs of higher-level experts [2]. The area of data warehousing has seen a lot of study and developments during the past two decades. Fig.1, illustrates the architect of a simple ware house used to store less amount of data. It was a lengthy road from an offline operational database to an integrated data warehouse, but we still have a long way to go. Currently, there are many areas in which we may improve, some of which are highlighted in this article. Data warehouses are relational environments for analyzing data, especially historical data. Data warehouses are used by businesses to identify patterns and connections in their data over time. Transactional environments, on the other hand, are used to process transactions on a continuous basis and are frequently used for order entry, financial transactions, and retail transactions [3]. They don't rely on past data; in fact, old data is often preserved or destroyed in OLTP settings to enhance efficiency. The autonomous data warehouse, which relies on AI and machine learning to remove manual chores and ease setup, deployment, and data administration, is the most current version of the data warehouse [4]. There is no need for human database administration, hardware setup or maintenance, or software installation with an as-a-service autonomous data warehouse in the cloud. The data warehouse is created, backed up, patched and upgraded, and the database is expanded or decreased automatically—all with the same flexibility, scalability, agility, and lower costs that cloud platforms provide. The autonomous data warehouse reduces complexity, accelerates implementation, and frees up resources, allowing businesses to concentrate on higher-value operations [5]. Oracle Autonomous Data Warehouse is a simple-to-use, completely autonomous data warehouse that grows flexibly, provides quick query performance, and doesn't need database management. Oracle Autonomous Data Warehouse is easy and quick to set up.

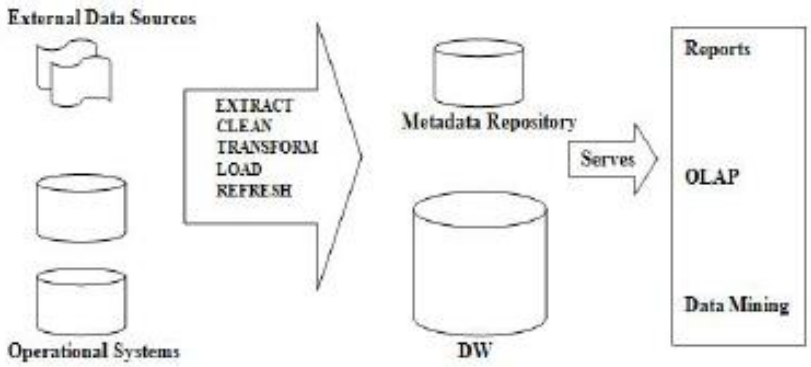

Fig. 1: Illustrates the architect of a simple ware house used to store less amount of data [6]**.**

Data warehousing initiatives still have a high failure rate, and even when they succeed, the time it takes is typically longer than anticipated. As a result, we still have a long way to go in terms of data warehousing and OLAP technology. We provide a comprehensive evaluation of data warehousing technologies in this article. We went through various types of data warehouse designs and data modeling. We looked at the data warehousing technologies and methods that are now accessible. Some of the most important research concerns are also mentioned. During the late 1980s and early 1990s, data warehousing emerged as a unique kind of computer database. The idea of data warehousing arose in response to a desire from upper management for analytical findings that a standard operational database could not provide effectively. The idea of data warehousing has gone through many basic phases as technology has improved and customer

demand has increased [7]. A data warehouse is a kind of data management system that is intended to facilitate and assist business intelligence (BI) and analytics operations. Data warehouses are designed primarily for querying and analysis, and they often store huge quantities of historical data. A data warehouse's data is often obtained from a variety of sources, including application log files and transaction programs [8]. A data warehouse is a system that collects and organizes huge quantities of data from many sources. Its analytical skills enable businesses to get important business insights from their data, allowing them to make better decisions. It accumulates a historical record over time that may be very useful to data scientists and business analysts. A data warehouse may be called an organization's "single source of truth" because of these qualities. The goal of data warehouses when they initially appeared in the late 1980s was to assist data flow from operational systems into decision-support systems (DSSs). These early data warehouses necessitated a great deal of redundancy [9]. The majority of companies have several DSS environments to suit their different consumers. Although the DSS environments shared a lot of the same data, the data collection, cleaning, and integration were often duplicated. Data warehouses developed from information repositories that supported conventional BI platforms into comprehensive analytics infrastructures that serve a wide range of applications, including as operational analytics and performance management, as they grew more efficien t[10].

DISCUSSION ON TYPES OF DATA WARE HOUSES

Iterations of the data warehouse have evolved through time to provide incrementally more value to the company. Each of these five stages has necessitated a growing number of datasets. The final three stages, in particular, highlight the need for even more data and analytics capabilities.AI and machine learning are now changing virtually every industry, service, and business asset, including data warehouses. Changes in data warehouse needs and capabilities are being driven by the growth of big data and the use of new digital technologies. The autonomous data warehouse is the most recent stage in this development, allowing businesses to extract even more value from their data while reducing costs and increasing data warehouse dependability and performance. Learn more about autonomous data warehouses and get started with your own. Data warehouses are distinct from data marts and operation data stores, despite the fact that they provide similar functions (ODSs). A data mart does the same tasks as a data warehouse, but with a much smaller scope—usually a single department or line of business. As a result, data marts are less difficult to set up than data warehouses. They do, however, create inconsistency since it may be difficult to manage and govern data consistently across many data marts.

Because ODSs are primarily used for day-to-day operations, their perspective of past data is restricted. They perform well as current data sources and are often used in data warehouses, but they do not allow historically rich searches. The cloud is used to ingest and store data from many data sources in a cloud data warehouse. On-premises servers were used to create the first data warehouses. On-premises data warehouses continue to provide many benefits today. They can provide greater governance, security, data sovereignty, and latency in many situations. On-premises data warehouses, on the other hand, are less elastic, and sophisticated forecasting is required to decide how to expand the data warehouse for future requirements. Managing these data warehouses may be difficult as well. The finest cloud data warehouses are self-driving and completely managed, allowing even novices to build and utilize a data warehouse with only a few clicks. Running your cloud data warehouse on-premises, behind your data center firewall, which meets with data sovereignty and security standards, is a simple approach to get started with your migration to a cloud data warehouse. Furthermore, most cloud data warehouses operate on a pay-as-you-go basis, allowing clients to save money. Distinct users throughout the company have different requirements for a data warehouse, whether they're part of the IT, data engineering, business analytics, or data science teams.

A contemporary data architecture satisfies these many requirements by allowing users to handle all kinds of data, workloads, and analysis. It is made up of architectural patterns that have all of the essential components integrated to operate together in accordance with industry standards. When creating a data warehouse, a company must first define its particular business needs, agree on the scope, and develop a conceptual design. The data warehouse's logical and physical designs may then be created by the organization. The logical design focuses on the connections between the items, whereas the physical design focuses on the most efficient storage and retrieval methods. Transportation, backup, and recovery procedures are all included in the physical architecture. The requirements of the end users are a major consideration in the design. The majority of end users want to do analysis and look at data in bulk rather than as individual transactions. End customers, on the other hand, often do not know what they want until a particular need emerges. As a result, sufficient investigation should be included in the planning phase to anticipate requirements. Finally, the data warehouse should be designed to allow for growth and development in order to meet the changing requirements of end users.

Cloud-based data warehouses provide the same features and advantages as on-premises data warehouses, but with the additional benefits of cloud computing, such as flexibility, scalability, agility, security, and cost savings. Cloud data warehouses enable businesses to concentrate exclusively on extracting value from their data rather than having to develop and maintain the data warehouse's hardware and software infrastructure. Data lakes contain a large amount of unprocessed, unstructured data that may be utilized for a specific purpose later. A data lake stores raw data from line-of-business applications, mobile apps, social media, IoT devices, and other sources. The structure, integrity, selection, and format of the different datasets are determined by the individual doing the study at the moment. A data lake may be the best option for businesses that require low-cost storage for unformatted, unstructured data from many sources that they plan to utilize for some reason in the future. The architecture of a data warehouse is determined by an organization's business processes, taking into account data consolidation across the organization with security, the level of query requirement management, Meta modeling and organization, warehouse staging area planning for optimal bandwidth utilization, and full technology implementation. However, a lack of quality in the data warehouse's information may lead to poor strategic choices. As a result, data warehouse information quality must be ensured, which is dependent on presentation quality, data quality, and data model quality (both physical and logical). Multidimensional modeling is generally recognized for data warehouse data modeling, and OLAP tools directly access multidimensional schemas of data warehouses to assist decision makers. As a result, the quality of the data model has a significant impact on the overall quality of the data warehouse. Facts and dimensions are organized in multidimensional schemas. The measurements for analysis along the dimensions are included in the facts. For better data representation, dimensions include characteristics, granularity levels, and hierarchies.

All of these structural components, as well as their relationships, influence the schema's complexity, which in turn influences the data model's quality. Previously, the quality of data warehouse conceptual models was regarded intuitive, but to improve objectivity, these intuitive concepts of quality must be replaced with a set of quantitative measurements. A metric is a method to consistently and objectively assess a quality element. Several writers have suggested criteria to assess the quality of conceptual data models for data warehouses, such as maintainability, understandability, and so on. These measures have been theoretically and experimentally verified.Fig.2, illustrates the data cube multi dimensional model used in data ware houses. As a result, in this article, we provide a systematic literature analysis of data model quality measures for data warehouses in order to understand the current state of the art and identify research gaps. The rest of the paper is structured as follows: The methods used to

perform SLR for our study field are described in Section 2. This document summarizes the different criteria suggested for assessing the quality of data warehouse conceptual data models. Deliberates on the SLR's results, expanding empirical evidence, data warehouse quality variables, and current research gaps. It is the framework that manages the storage, retrieval, alteration, and deletion of data in the Data warehouse by converting information from one form to another step by step. It refers to the different resources available, such as software resources for data warehouse maintenance and management. The performance of the data warehouse system is directly related to the quality of the resource architecture.

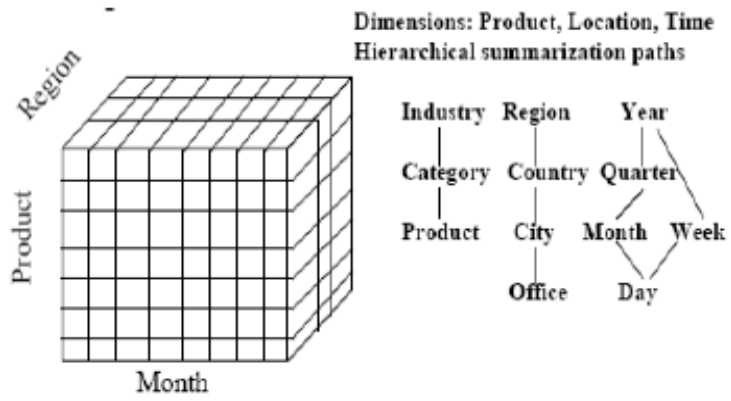

Fig. 2 : Illustrates the data cube multi dimensional model used in data ware houses.

The above categorization provides an overview of the many types of attributes that should be considered when designing a data warehouse architecture. However, when we discuss the overall design of a data warehouse, we typically refer to a multi-tiered architecture. The following diagram depicts a typical three-tier architecture. We are quite familiar with entity relationship modeling for regular operational databases, but for portraying the Data warehouse, we utilize a different method known as dimensional modeling, which employs the idea of fact and dimension. Essentially, dimensional modeling is a method for logically structuring data in a standard, understandable framework for high-performance access that consists of a fact table with a multipart key and a collection of smaller tables known as dimension tables. The fact table contains two kinds of columns: one for facts and the other for foreign keys. Numeric measurements are what facts are. The looked up reference table is also known as a dimension table. It is a table that contains information on the perspectives or entities that an organization wishes to keep track of the facts and dimensions are combined, we obtain a data cube, which is a multidimensional representation of the data.

However, unlike the geometric cube, this cube is n-dimensional and not limited to three dimensions. When compared to the traditional relational data modeling method of utilizing ER diagrams, multidimensional data modeling offers many benefits. The illustration depicts a data cube that considers sales volume as a function of product, month, and region. All publications that addressed the quality of conceptual data models in data warehouses and provided metrics for the quality characteristics that influence such data models were deemed relevant. We performed our main search to extract studies from sources of information based on our research questions, and originally 18088 papers were obtained. The papers were first weeded out based on their titles. Only 453 research remained after excluding papers relating to physical and logical data models. Around 100 articles were excluded since they only discussed the conceptual model of data warehouses and not its measurements. Then, based on their abstracts, we screened out 65 studies that were not relevant to our study. Finally, complete texts were reviewed, and based on

exclusion and inclusion criteria, a list of 22 papers was determined to be relevant for our study. After exploring internet databases, we found a total of 22 papers that were relevant to our study.

More over half of the articles in this study were published in journals, according to the distribution. The bulk of the remaining papers were thereafter published in conference proceedings, with just a few being published in workshops. The first step in creating a data warehouse is to extract and clean data. The most essential element of any database is the quality of the data in order to obtain the required result as quickly as possible. We now have a variety of tools for data extraction and cleaning, but none of them are as efficient as we would want. We obviously need quality data to obtain quality results, therefore extraction and cleaning of data to acquire quality data is a hot study topic for data warehouses. Data transformation and integration is another topic that should be investigated further since data warehouses are built utilizing data from a variety of sources, thus we should have effective solutions accessible now. Because various databases have different schemas and formats, converting them to a comparable format before loading into the data warehouse is one of the most essential jobs in data warehousing. Data transformation with the least amount of mistake and information loss is still a long way off. Another area where we have a lot of room for improvement is data warehouse maintenance. To effectively handle the growing size of the data warehouse, we should search for improved maintenance methods, as well as better software and hardware. Metadata management should also be investigated further. Any system's primary goal is to get the result as quickly as possible. We have many technologies in the data warehouse for efficient query processing, but they still need to be enhanced significantly to reach the necessary efficiency. More study on query processing is required.

CONCLUSION AND IMPLICATION

The foundation of an automated decision support system is data warehousing. Although much study has been done in the last decade, there are still many problems that need to be addressed in the future. At the moment, one of the most popular study topics is performance and management. We've compiled a list of the most recent data warehousing solutions and organized them into logical categories. The data warehouse architecture is also separated conceptually, and a representative model of the architecture is provided. We looked at some of the most important study topics, such as data cleansing, data transformation, maintenance, and query processing efficiency. We identified key data warehousing research topics and things to undertake in the future to get the most out of our data warehousing.

A REVIEW ON MACHINE LEARNING AND IT'S ALGORITHMS

Dr. Kashif Qureshi*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: kqureshi.cse@sanskriti.edu.in

ABSTRACT

As technologies is conquering every current sector in today's day. Machine Learning has emerged amongst one of the most challenging and most utilized technologies globally. Machine Learning is essentially training computers to do the real-time tasks without human involvement. There have been numerous innovations and advancements in deep learning which has also affected human life. Machine Learning has its implications in many sectors such as medical, business, finance, robotics, engineering or several more domains. Machine Learning algorithms of many kinds are available which are utilized in different models. These algorithms play essential part in every model or project they are utilized. All these implementations, types and methods have been covered in this article. This article provides overview of machine learning as well as its algorithms. It outlines how deep learning is anticipated to dominate every current sector. It also discusses what are all the expectations of future from machine learning in approaching time period or how it is going to develop human life.

KEYWORDS:*Algorithm, Data, Machine Learning, Model, Result.*

1. INTRODUCTION

Machine Learning is the process of training computers to do various jobs without explicitly programming them. It is the area of engineering which provides robots the capacity to learn and execute tasks without human involvement. In machine learning models training data is given to the model. The model examines and observes different aspects of the data given to it and then learns from the trained data. After that test data is given to the model in which the model needs to provide findings depending on its learning. The model generates estimates based on training data or provides output results. Then the accuracy level of model is evaluated by using different methods such as Logistic Regression, Decision tree or Random Forest Tree. On whatever method the model provides better results is chosen for real time usage after evaluating its applicability level[1]. Figure 1 shows the type of Machine Learning which are discussed in details below.

1.1.Types of Machine Learning:

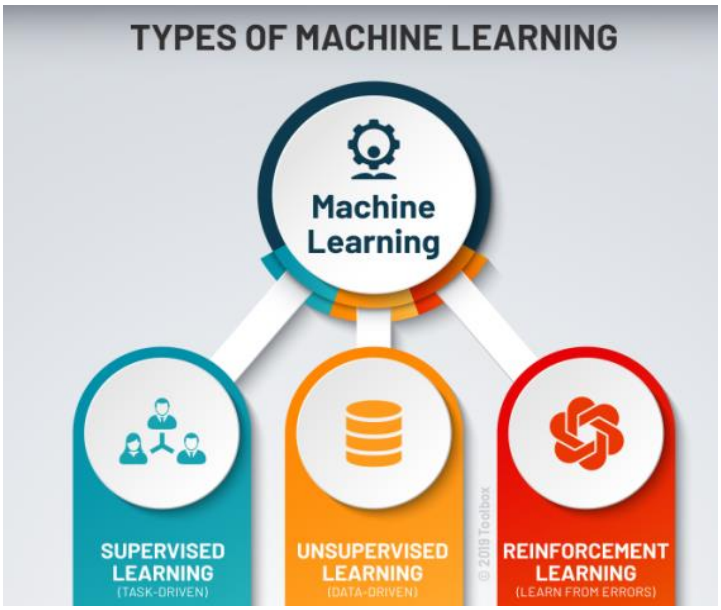

Figure 1: Illustrate the Diagram Show Types of Machine Learning[2].

1.2. Supervised Learning:

Supervised Learning is the kind of machine learning in which the model is supplied with labels and features along with the data. In supervised learning we train our model using labeled and tagged data. Labeled data is the data which contain both input and output variable in it. Based on this data the model generates predictions about future outcomes which are evaluated using different methods. For the test results to be correct the training data needs to be big enough so that model is able to identify patterns generated in the data and can respond according to that. After providing correct results in testing data the model may be further trained by comparing the projected data of model with actual results and mistakes gained can be utilized in changing the model. After that we offer fresh set to test it. When we have target/ dependent/output variable along with the provided data it is known as supervised machine learning issue. It is task focused since it concentrates on a specific job until it delivers correct results[3].

Supervised learning issues may be divided in two sections depending on the kind of output variable:

Classification: It covers issues under supervised learning when output has specified variables which implies output variable have discrete values.

Regression: It is the type of learning in which output variable is always a continuous value. Its primary aim is to anticipate the output value as near as it may be the real output value. After obtaining output values from model, these values are compared which real output results and error rate is determined.

1.3. Unsupervised Learning:

Unsupervised learning is simply the reverse of supervised learning. There is no such labeled as well as tagged data given to the model. Instead in unsupervised learning a huge quantity of data which is unorganized and indeed the tools to interpret that data are given to the model such that model itself figure out now and learn to arrange the data in patterns, categories or clusters which people can understand.

What makes the unsupervised learning more relevant is that most of the data available globally is unlabeled and untagged. Unsupervised learning is entirely dependent on the data given to it. The outcomes it provides are entirely data driven.

1.4. Reinforcement Learning:

It is totally different from supervised or unsupervised learning. In it there is no training data given to the model. In it the model needs to determine by itself what to do and how to accomplish the specified job. In it the model attempts to discover the optimum solution to the given issue. The model performs consecutive steps one by one determining by itself all the moves. In it the output entirely relies upon the condition of input and each future move is dependent on the outcome of previous step. One of the most prominent example of reinforcement learning is Chess in which each single move has varied consequences[4].

1.5. Semi-supervised Learning:

As the name indicates it contains few characteristics of the supervised learning. In semi supervised learning the model is supplied with a small quantity of labeled data and a big amount of unlabeled data as training data. The method followed in it is that initially the model will cluster the unlabeled comparable data using unstructured machine learning techniques and then it will label remainder of the data using provided labeled data. This is a type of idea as we see in schools where instructor teaches few questions as well as explains them to pupils and then provide remainder of questions to practice and answer by themselves. Figure 2 shows the various applications of Machine Learning used in several areas which are discussed below one by one in detail[5].

1.6. Applications of Machine Learning:

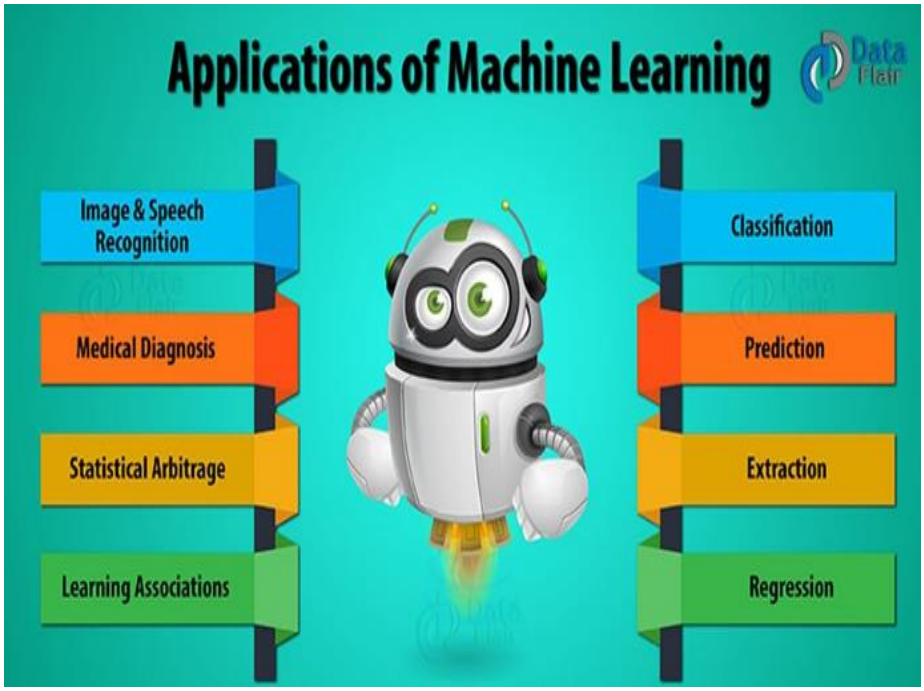

Figure 2: Illustrate the Applications of Machine Learning in various areas[2].

1.7. Image Recognition:

It is one of the most significant and frequently used applications in machine learning. Image recognition is essentially the process or method of recognizing objects, items, people, pictures, logos, buildings and locations. There are numerous phones and laptops today which utilize face detection unlock system, it is only feasible because of image recognition application of machine

learning. It is employed at in CCTV cameras to capture criminals and odd behaviors. It is utilized at numerous police stations and criminal investigation agencies. It is used in Google pictures application for grouping images of individuals. There are numerous applications in which we may simply scan the item and obtain all relevant information about it. The major stages involved in this process are collecting of data, structuring of data and then creating a model which can forecast the outcomes and utilize it for image recognition process.

1.8. Speech Recognition:

Voice Recognition is similar to Image recognition. It's only here voice of a person is recognized. It is described as the capacity of gadgets to react to spoken instructions. Nowadays there are lots of gadgets which utilize voice recognition technology. In Android phone there is Google voice assistant which operates on voice commands and makes it simple to work. There are speakers, headphones and earphones and many other gadgets which are created with in-built speech recognition technology in them. There are keyboards which are voice aided , they translate voice instructions into text messages and may be used for chatting, searching and many other tasks. The voice recognition feature makes it simple for users to automatically plan their appointments, meeting, sending mails, maintaining music playlists, playing songs, video games, buying online meals, or many other similar activities can be done on one voice command. Apple has developed its own Artificial Intelligence based chatbot called Siri which is available in all the iPhone and operates on voice requests. Similarly, Amazon offers Alexa, its own created program which operates on voice command. So essentially Speech recognition system has its use all over globe in different sectors which has made lots of jobs easier to complete and have made human life better.

1.9. Traffic Prediction:

Currently, road congestion becomes a significant issue worldwide. People have to wait for several hours trapped in traffic for getting to their job locations. In certain highly crowded cities circumstances have gotten so bad that a journey of half hour often takes 2 hours or more. Seeing these issues individuals have come up with solutions among which the most helpful and beneficial is traffic prediction system. Google maps is an application designed for assisting users discover quickest routes based on source and destination location given. It utilizes Dijkstra's method of determining the shortest path or path among two points. Google Maps estimates the road or path which has least traffic and takes least time giving the user the best way to the destination. It forecasts traffic conditions including whether road is highly crowded or sluggish traffic is present based on which user may select which route to take. It also assists in revealing real time location of a person. It assists in calculating how much it takes for getting to a specific destination from present or any source location[6]. Thus, traffic prediction system assists individuals saving their time as well as reaching the intended destination.

1.10. Autonomous Vehicles:

As the name indicates autonomous automobiles are the cars which are qualified to drive without human involvement. These vehicles contain sensors based on which they detect the environment and respond appropriately. In these autonomous vehicles there is no need of presence of people at all neither as an operator nor as a passenger. These vehicles can go anywhere without any people supervision in the same manner that a person can. The operation of these vehicles entirely relies upon the sensors, actuators, algorithms, Based On machine learning technologies present in them. They have radar sensors that are used to detect the presence of adjacent cars. These have videos cameras placed in them via which they can identify people, traffic light signals and interpret road signs. Presence of Lesser sensors makes it simple to handle lane crossings, road margins and light detection. Ultrasonic sensors located in the wheels are utilized to identify curbs

when parking the vehicle. These vehicles are currently through the testing process as well as will be out to use very soon having great effect on lives of people[7].

1.11. Online fraud detection:

There are many instances of online fraud or online money theft which makes consumers concerned and think twice before completing any online transaction. Whenever someone conducts an online transaction there are numerous methods by which the money may be taken by some third party. It includes individuals with false accounts or fake ids similar to people you know and then they take money from the user account in the midst of the transaction. To guard and prevent from these frauds Machine Learning application Feed Forward Neural network has been created which identifies which is able to identify whether a transaction is real or fraud. It has made internet transactions considerably more safe and secure[8].

1.12. Medical Diagnosis:

Similarly, to different sectors machine learning plays a crucial part in medical profession too. There are many gadgets in which machine learning (ML) algorithms are employed which aids in treatment of different illnesses. There are devices such as DeepGene which are integrated with Machine learning techniques which help in identifying the tumor at early stage so that appropriate therapy can be given to the patient. Pathology is a medical field in which ML is employed in increasing blood precision and in mapping sick cells. In dermatology ml algorithms are used to treat acnes, fungus and seborrheic dermatitis. Mental Health problems of many individuals are addressed by early identification of mental illness signs utilizing ML methods. There are many different such sectors of medical field in which machine learning methods are utilized for treatment of patients[9].

1.13. Automatic Language Translation:

It is essentially the process of translating one language into another. Each nation has its own distinct language. In reality, in nations like India there are various languages used in different states. Well clearly a single individual cannot know all the languages therefore if someone goes to some another nation or state he needs to speak in the local language of that people which cannot be done without the need for a translator's assistance. Here comes the role of Automated Language Translation method. People do not need to have a translator with them anymore as Automatic language translation converts the content into any language of user's choosing. Google has created Google Neural Machine Translation which can convert the text into a language familiar to the user, this process is known as automated translation. The technology utilized in this procedure is sequence to sequence learning algorithm[10].

1.14. Algorithms of Machine Learning:

1. Linear Regression: Regression Analysis is a supervised machine learning method. It is used to conduct regression tasks. It is used to compute numbers like as total number of people, cost of homes, etc. based on continuous variables. In this a connection is created between dependent or independent variable. It is expressed as Y= a *X + b where Y is the Dependent variable, an isthe slopes, X is the independent factor as well as b is the intercept. Figure 3 shows the linear regression graph Height of People with their body weights.

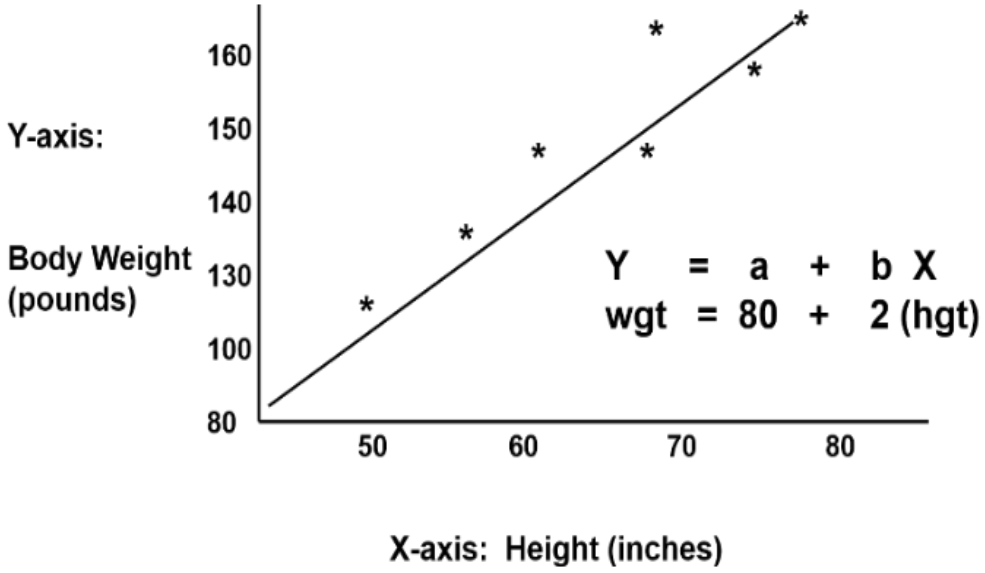

Figure 3: Regression graph Height of People with their body weights.

1.14.1. Logistic Regression:

Regression Logistic is a classification category supervised machine learning method. Its output variable only accepts separate values for a set of characteristics. It is used to utilize functions to forecast the likelihood of an occurrence. Because it forecasts probability, its output value is always between 0 and 1.

1.14.2. Decision Tree:

This is another supervised learning method that is usually used to solve classification issues but may also be used to solve regression difficulties. The data is represented using a tree structure, with each leaf node representing a class label and all interior nodes representing characteristics. At first, the whole data set is seen as a root. Feature values should ideally be categorical, but if they aren't, they are transformed to discrete values. It is utilized in a variety of fields, including business, law, engineering, and many more.

1.14.3. Machine Learning's Obstacles:

- Data gathering is a time-consuming and expensive procedure. It takes a long time, or not everyone has the time or patience to devote a significant portion of their time to such a task.
- Once the data has been collected, it must be processed utilizing a variety of data annotation techniques. This procedure is entirely responsible for the model's correctness. As a result, even a little error may derail the whole operation.
- Each technology has fresh upgrades and improvements that not everyone can comprehend and apply in current technologies.
- It takes months to develop a good model or project that necessitates patience, and today's fast-paced generation lacks the patience to finish even a single job.

2. DISCUSSION

Machine Learning has a broad range of applications all around the globe. With its discoveries and advancements, it has changed the whole technical sector. It has made inroads into a wide range of disciplines, including medicine, finance, business, physiology, psychology, and a variety of others. It has a wide range of applications, including robotics, speech recognition,

image recognition, traffic prediction, self-driving cars, automated vehicles, pathology, medical diagnosis, fully automated language translation, product recommendation, online fraud detection, email as well as spam filtering, and many more. This article goes through all of these applications as well as the methods utilized in them, such as logistic regression, decision trees, and linear regression. Machine learning technologies have proven to be a benefit in today's fast-paced environment, according to the author.

3. CONCLUSION

Machine Learning is a huge area packed with life-changing innovations that have had far-reaching effects on human lives that no one could have predicted. There are many machine learning advancements that are assisting in the saving of thousands of lives. Diagnostic machines, ultrasonic machines, X-ray machines, and other equipment that aid in the identification and treatment of different illnesses.

Machine learning has become a critical component of every business. It has made every job so much simpler and faster than it was before. Machine learning algorithms have shown to be very useful and simple to utilize in performing a variety of jobs. Because machine learning is utilized everywhere, it seems that it will continue to expand and spread in the future. It has high future aspirations;thus, ML devices will have a lot of potential in the future.

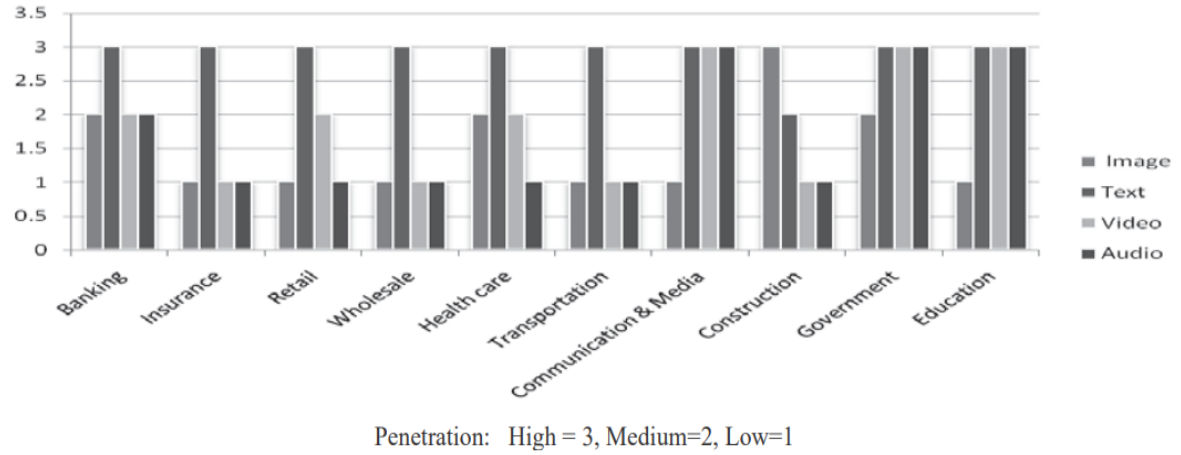
ABSTRACT

Big Data is a new idea that covers cutting-edge methods and technology for analyzing huge volumes of complicated information produced at different speeds and from diverse sources. Data mining methods are proving to be very useful in the field of Big Data Analytics (BDA), since dealing with large amounts of data poses significant difficulties for applications. The capacity to extract valuable information from massive databases is known as big data analytics. The significance, difficulties, and uses of Big Data in many areas, as well as the various methods utilized for Big Data Analysis utilizing Data Mining techniques, are discussed in this paper. The results of this study provide scholars with important information about the major trends in Big Data research and analysis utilizing various analytical domains.

KEYWORDS:*Big Data, Big Data Analytics, Big Data Application, Data Mining.*

17. INTRODUCTION

In our digital age, analysts have access to massive quantities of data. Big Data is a phrase used to describe a collection of unstructured, semi-structured, and structured information that are challenging to gather, manage, process, or analyze using traditional database software tools and technologies due to its volume, complexity, and pace of development. Text, video, picture, music, website log files, blogs, tweets, location information, sensor data, and more formats are used. Smart and scalable analytics services, programming tools, and apps are required to extract valuable information from such large datasets. The data comes in a variety of forms, including audio, video, pictures, and text, and it varies by industry. Text data is handled by the banking, insurance, and health-care industries. Audio and video data are heavily influenced by communication and media. Fig. 1 demonstrates how, based on the kinds of data produced and stored, there are differences in the quantity of data stored in various sectors.



Penetration: High = 3, Medium=2, Low=1

Fig. 1: Various sectors produce and store different kinds of data.

Data mining, also known as Knowledge Discovery in Databases (KDD), is an analytical technique used in a variety of fields to find meaningful connections between variables in big data sets. Analyzing large amounts of data in a short amount of time may lead to new insights and theoretical ideas. Big data has the potential to help businesses improve their operations and make quicker, more informed choices.

Data mining is the process of examining and analyzing large amounts of data in order to uncover patterns in big data. The methods were derived from statistics and artificial intelligence (AI), with a dash of database management tossed in for good measure. Data mining usually has one of two goals: categorization or prediction. The goal of classification is to organize data into groups. A marketer, for example, may be interested in the characteristics of individuals who reacted to a promotion vs those who did not. There are two types of classes. The goal of prediction is to forecast the value of a continuous variable. A marketer, for example, may be interested in forecasting who would react to a campaign.

18. LITRATURE REVIEW

This part includes a thorough assessment of the literature from a variety of publications, academics, and other online sources. It is split into two halves. The first section is an overview of Big Data's significance, difficulties, and applications in different areas. The second section covers the various methods to Big Data Analysis and their results using various Data Mining techniques. Wei Fan et al. provided an overview of big data mining in 2012, including its current state, debate, and future predictions [1]. Kaur et al. discussed a variety of Big Data problems [2]. They also discussed how Big Data analysis may help address certain operational, financial, and commercial issues in aviation that were previously intractable due to economic and human resource limitations.

S.Vikram et al. demonstrated the five aspects in which big data varies from ordinary data: volume, velocity, variety, value, truth, and complexity [3]. They discussed how large data systems are handled using the Hadoop framework. The authors also focused on the difficulties that businesses must confront when dealing with Big Data, such as data privacy, search analysis, and so on. D. Agarwal published a thorough research on data mining, models, issues, and applications in 2013 [4]. D. Kishor proposed changing the fundamental concept of Big Data from 3V to 3C in order to better explain Big Data analytics using mathematical and statistical methods [5]. In 2014, R Gupta et al. presented an overview of big data, its significance, big data technology, and how big data can be used to self-organizing websites, which can be extended to the area of advertising in businesses [6].

Big Data's content, scope, techniques, privacy, security, samples, benefits, and difficulties were all discussed by S. Sagiroglu et al [7]. They discovered that the difficulties were not only in collecting and managing data, but also in extracting valuable information from that data. In 2014, Xindong Wu et al. proposed the HACE theorem, which defines the characteristics of the Big Data revolution and offers a Big Data Processing model from a Data Mining perspective [8]. Healthcare, networking security, market & business, education system, communications, and other real-time uses of big data were given by the authors Sabia et al [9]. B. Thakur et al. reviewed several kinds of big data in 2014, as well as major difficulties in big data management and analytics that emerge from the nature of data, which is vast, varied, and changing [10]. In July 2015, the author Vatsal Shah examined huge amounts of unstructured data in the form of video and proposed a solution utilizing the Hadoop platform [11].

19. DISCUSSION

19.1. Big Data:

Big Data encompasses not just a huge amount of data, but also additional characteristics that set it apart from the notions of "extremely big data" and "massive data." In reality, there are many definitions of Big Data in the literature. “Big Data technologies represent a new generation of technologies and architectures intended to cheaply extract value from extremely large quantities of a broad range of data, by allowing high-velocity collection, discovery, and/or analysis,” according to the International Data Corporation (IDC). Big Data is defined by the McKinsey Report as "data sets that are too large for traditional database software tools to collect, store, manage, and analyze."

The three Vs, or Volume, Variety, and Velocity, are often used to characterize Big Data. The size of the data is represented by the volume. Velocity refers to the rate at which real-time data is generated and delivered. Because data originates from a variety of sources, as illustrated in Table 1, the data becomes too large.

TABLE 1: DIFFERENT TYPES OF BIG DATA & ITS SOURCES.

Data Types	Sources	Formats
Structured	Business Applications such as retail, finance, bioinformatics etc.	RDBMS, OLAP, Data warehousing
Semi-structured	Web Applications such as web logs, email, webpages	XML, CSV, HTML, RDF
Unstructured	Images, Audio, Video, Sensor data, Blogs, Tweets etc.	User generated text content

The following Big Data definitions offer a collection of tools for comparing Big Data to conventional data analytics. Table 2 summarizes this comparison using the 3Vs (Volume, Velocity, and Variety) dimension.

TABLE 2: COMPARISON OF BIG DATA AND TRADITIONAL DATA.

Characteristics	Big Data	Traditional Data
Volume	Terabyte, Petabyte, Exabyte	Gigabyte
Velocity	More rapidly	Per hour, day
Variety	Structured, Semi-structured or Unstructured	Structured
Data integration	Difficult	Simple
Data access	Real time or batch	Interactive
Source of data	Fully distributed	Centralized

The study of Big Data is at the heart of contemporary research and industry. Because a large quantity of data is produced from a variety of heterogeneous sources, storing, extracting, transforming, and loading it becomes challenging. According to a recent study, Google receives over 4 million search queries per minute, e-mail users send over 200 million emails, YouTube users upload 72 hours of video, Facebook users share over 2 million pieces of content, Facebook processes 350 GB of data per minute, more than 570 websites are created per minute, and Twitter users send 277,000 tweets per minute. According to estimates, the produced data constituted approximately 5 exabytes until 2003, 2.7 Zettabytes until 2012, and is projected to grow fourfold by 2016. Astronomy, social media/entertainment and networking sites, life sciences, healthcare, video surveillance, government data, sensor technologies and networks, mobile devices, and other fields all have large datasets. The Fig. 2 shows the data in Exabyte (EB) for the year 2005-15 [12]. The quantity of data was rapidly expanded throughout this time owing to the major contribution of Big Data Analytics, as seen in this graph from 2005 to 2015.

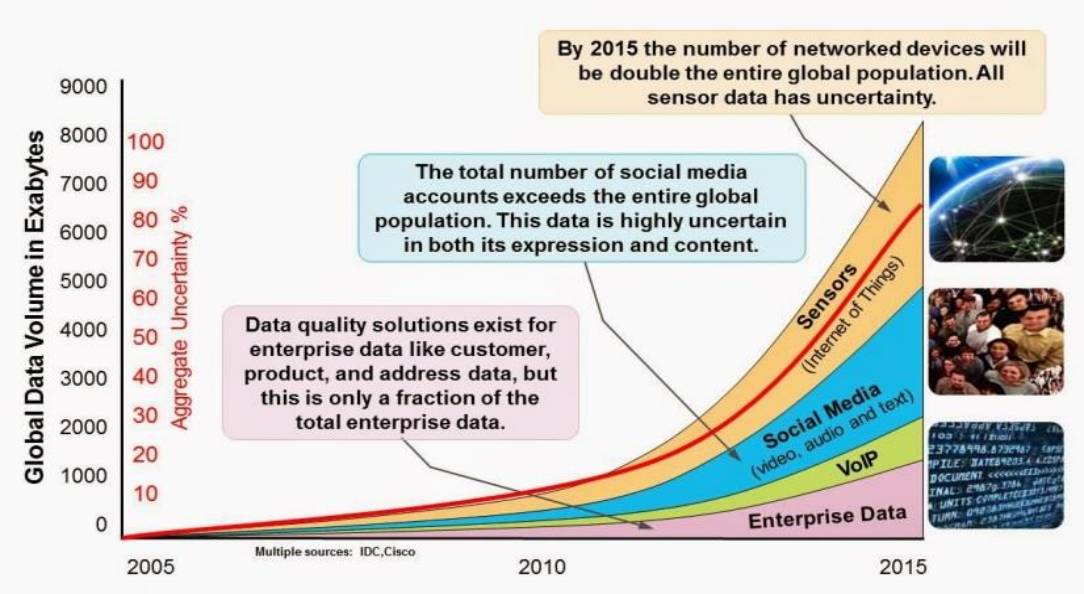


Fig. 2: Illustrates exponential data growth [12]**.**

Several difficulties that businesses or media must confront when dealing with Big Data include capturing Big Data, its length, storage, sharing, analysis, display of enormous data, and, of course, the most essential technology. For this, new architecture, algorithms, and methods for implementation are required. It also requires technological expertise. As a result, specialists are required to deal with Big Data using this new technology. Technical Challenges, Data Management and Sharing, Privacy, Security and Trust, and Misuse of Big Data are all issues that must be addressed while analyzing Big Data.

19.2. Data Mining:

Because there is a lot of data out there with a lot of hidden knowledge, data mining has become a hot topic in the information business. Indeed, we might argue that data mining is a relatively recent scientific study topic in the fields of statistics, machine learning, database management science, and visualization that aims to find and display information in a way that humans can comprehend. The goal of data mining is to extract hidden information from huge amounts of data. This information may assist and support organizations in making better and more informed choices. The potential for data mining algorithms to generate millions of patterns and rules is enormous. Knowledge is represented as an intriguing pattern. The discovery process may be guided by objective or subjective measures of pattern interestingness. There are a variety of common models that may be utilized to solve various data mining issues. Among them are Nave Bayes, Decision Trees, Neural Networks, Support Vector Machines, and K-means.

19.3. Big Data Analytics & Process Model:

Big Data Analytics is a tool that allows businesses to analyze huge amounts of data in order to find patterns and other valuable information. The quantity of data has grown rapidly over the last decade, from 2005 to 2015. This is due to the substantial contribution of Big Data Analytics. The following are examples of technical advancements in Big Data storage, processing, and analysis:

- In recent years, the cost of storage and CPU power has dropped dramatically.
- The creation of new frameworks, such as Hadoop, that enable users to take use of distributed computing systems capable of storing huge amounts of data and processing it in a flexible parallel manner.
- Datacenters and cloud computing's flexibility and cost-effectiveness for elastic processing and storage.

The Process model for Big Data analytics is the focus of this section. The entire model is split down into two sub-processes: data management and analytics, which are further separated into five phases as shown in Table 3.

TABLE 3: PROCESSES FOR EXTRACTING INFORMATION FROM BIG DATA.

Big Data Processes	
Data Management	**Analytics**
1. Acquisition & Recording 2. Extraction, Cleaning & Annotation 3. Integration, Aggregation & Representation	4. Modeling & Analysis 5. Interpretation

TABLE 4: TAXONOMY OF BIG DATA ANALYTICS.

Analysis Domain	Characteristics	Approaches	Techniques	Source of Data
Structured Data Analytics	Structured records, less volume and real time.	Statistical Analysis	Statistical Machine Learning. RDBMS, OLAP, Data Warehouse	Business & Scientific Data.
Text Analytics	Language dependent, Unstructured, Semantic, Rich Textual.	Text Mining, Opinion mining or Sentiment Analysis, Summarization, Question Answering System, Natural Language Processing (NLP).	Clustering, Neural Network, SVM, Decision Tree, Naïve Bayes	Emails, logs, Blogs, Twitter, Facebook, Webpage, Corporate documents, Government Rules and Regulations etc.
Web Analytics	Integration of Text and Hyperlink, Symbolic, Metadata	Web Content Mining, Web Usage Mining, Web Structure Mining	Classification and Clustering.	Various Web Pages
Multimedia Analytics	Collection of Audio, video & image	Indexing & Retrieval, Summarization, Error detection, annotation	Multimedia annotation, Video Summarization, audio Summarization	User generated multimedia, surveillance, healthcare media, corporation produced multimedia.
Mobile Analytics	Fragmented data, person specific	Monitoring	Location based mining	Mobile phone applications, sensors

The most crucial step of the Big Data Process model is data analysis. This model's aim is to derive valuable insights and conclusions that will aid in decision-making. The goal of data analytics is to collect as much information as possible that is relevant to the topic at hand. The researcher discovered that the produced data is separated into different areas of Big Data applications in Big Data Analytics. Structured Data Analytics, Text Analytics, Web Analytics, Multimedia Analytics, and Mobile Analytics are a few of them. Table 4 highlights all five kinds of Big Data applications, which are grouped by data type and include data features, various methods and techniques, and data sources. Data analytics deals with information about a phenomena acquired via observation, measurement, or experimentation.

20. CONCLUSION

In the past decade, the exponential increase in data capacity and complexity has prompted much study in the area of big data technology. We have attempted to synthesize the current literature review year by year in the field of Big Data and its analysis using various analytics methods in this article. Text analytics, which is regarded as the next generation of Big Data, is now widely acknowledged as a mainstream method of extracting valuable information from millions of opinions posted on social media. Because of the strong interest in real-time data of rich picture and video material, video, audio, and image analytics techniques have scaled with advancements in machine vision, multilingual voice recognition, and rules-based decision engines. They are possible answers to a variety of economic, political, and social problems. Our future work will mainly concentrate on the Big Data analytics method mentioned above, which will be implemented utilizing different data mining approaches.

USING ELECTROCHEMICAL SEPARATION AND DEGRADATION METHODS, WATER CONTAMINATION CAUSED BY PHARMACEUTICAL RESIDUES MAY BE REMEDIED

Dr Durgesh Wadhwa*

SBAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: hodchem@sanskriti.edu.in

ABSTRACT

Due to substantial improvements in electrode materials and connection with low-cost renewable energy sources, cleansing and disinfection of waterways using direct or integrated electrochemical processes has become a highly attractive option in recent years. Many electrochemical methods are now available for the treatment of waterways polluted with refractory organic pollutants, such as pharmaceutical micropollutants, which have become a significant environmental problem. Recent studies have looked at how other key techniques, such as ozonation and sophisticated oxidation processes, may help remove pharmaceutical residues. The electrochemical techniques developed for the treatment of pharmaceutical residues from both synthetic solutions and actual pharmaceutical wastewaters are discussed here. The first step is to introduce electrochemical separation technologies such as membrane technologies, electrocoagulation, and internal micro-electrolysis, which exclusively separate contaminants from water. Anodic oxidation, electro-oxidation with active chlorine, electro-Fenton, photoelectro-Fenton, and photoelectrocatalysis, among other methods, are explored further. The potential solar photoelectro-Fenton method invented and further developed in our laboratory is emphasized and described in particular. The comparison of various techniques and materials allows for the decrease of total organic carbon or the reduction of chemical oxygen demand from polluted waters. The breakdown pathways for certain medicines are also discussed.

KEYWORDS:*Electrochemical Technologies, Electro-Oxidation, Electro-Fenton, Pharmaceuticals, Solar-Assisted Processes, Water Treatment.*

1. INTRODUCTION

Pharmaceuticals have gotten a lot of attention in the past 15 years as possible bioactive substances in the environment. They are classified as emerging contaminants in waterbodies because they are still uncontrolled or are in the process of becoming regulated, despite the lack of directives and legal frameworks. These chemicals, as well as their bioactive metabolites, are continually delivered into the aquatic environment, where they are identified at trace quantities

and become pseudo-persistent. In reality, it seems that the majority of urban wastewater contains therapeutic chemicals. This has an impact on water quality and drinking water sources, as well as posing a long-term danger to ecosystems and human and animal welfare [1] .

Several reviews have documented the presence and destiny of medicines in the environment, where they are ubiquitous in soil and water. Emissions from manufacturing facilities, direct disposal of overstock medicines in homes and hospitals, excretion from urine or feces following drug delivery to people and animals, and water treatment in fish farms all contribute to this pollution [2].

Veterinary medicines, for example, pollute soil directly via manure, as well as surface and ground waters through field runoff. Pharmaceuticals persist in the environment mostly due to inadequate sewage treatment plant (STP) removal, with between 60% and 90% of them persisting after biodegradation, deconjugation, sorption, and photodegradation processes. The biorecalcitrantunmetabolized and metabolized pharmaceutical residues in the STP effluents are subsequently discharged into the receiving surface waters, mostly rivers. Pharmaceuticals discharged into the environment have the potential to cause toxicity at any level of the biological hierarchy, but their impacts on living things are still unknown. For example, it is well recognized that certain medicines, even at low concentrations, may induce long-term, irreversible changes in the genome of microorganisms, increasing their resistance to them. Furthermore, these pollutants are often found in complicated combinations, resulting in "drug cocktails" whose toxicity is difficult to anticipate, such as beta-blockers. Some medicines, on the other hand, have been labeled as endocrine disrupting chemicals (EDCs) because they damage the human endocrine system [2].

The aforementioned factors highlight the necessity for medicines and their metabolites to be completely removed from aquatic systems to prevent potential toxicity and other harmful health consequences. Traditional methods such as bioremediation and physicochemical treatments such as coagulation, volatilization, adsorption, sedimentation, and filtration cannot completely eliminate these contaminants in STPs [3].

Chlorination and/or UV irradiation are used in most STPs to disinfect final effluents; however both methods have poor oxidation capacity, and trace organic contaminants are resistant to their action. The use of ozonation and advanced oxidation processes (AOPs), which are extensively utilized for disinfecting reclaimed water, for treating pharmaceutical residues, and for cleaning pharmaceutical wastewaters, has been the focus of recent study. AOPs are ecologically friendly chemical, photochemical, or electrochemical techniques that use the hydroxyl radical (•OH) as the primary oxidant and are produced in situ [4].

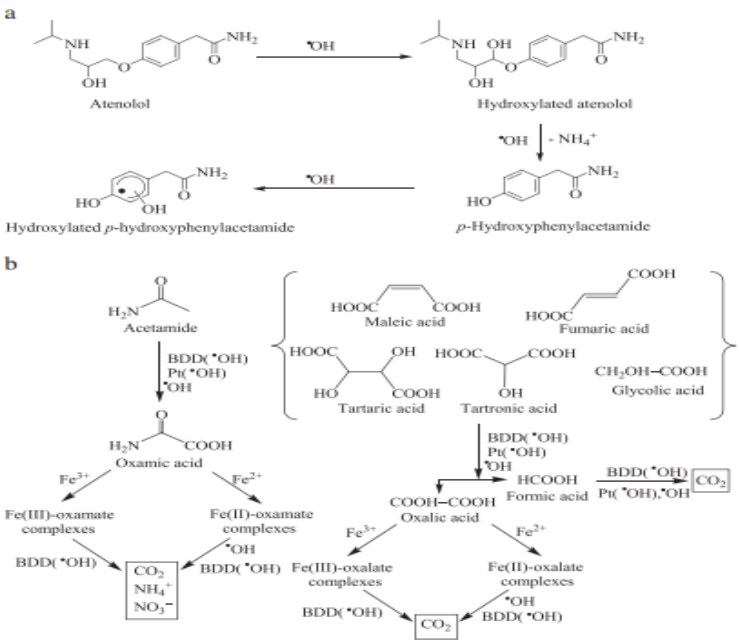

Figure. 1. (A) Initial reaction sequence proposed for the EF degradation of atenolol using an undivided Pt/carbon felt cell. . (b) Reaction path for the mineralization of carboxylic acids formed during the same treatment using combined Pt/GDE-Pt/carbon felt and BDD/GDE-Pt/carbon felt cells

2. DISCUSSION

The efficacy of ionizing irradiation in degrading medicines and personal care items is influenced by solution pH, dose rate, and water matrices, according to a recent study. In comparison to UV-based AOPs, gamma irradiation has demonstrated greater penetration and, as a result, enhanced production of hydroxyl radicals and hydrated electrons to aid in pharmaceutical breakdown. Although increasing the dosage of single gamma irradiation enhanced carbamazepine breakdown, adding peroxymonosulfate caused it to completely degrade, owing to the existence of hydroxyl radicals, per hydroxyl radicals, and superoxide radical anions.

Another carbamazepine research looked at the effectiveness of combining electron beam irradiation with hydrogen peroxide in the absence of H2O2; the scientists discovered that an electron beam irradiation dosage of 1 kGy may result in carbamazepine breakdown of up to 90%. The degradation rate increased to 95% in the presence of 10 mM H2O2. The degradation rate decreased when the H2O2 concentration was increased to 50 and 200 mM, suggesting that an adequate H2O2 concentration is required examined the efficacy of electron beam radiation on carbamazepine degradation in the presence of various ions and water matrices [5].

Due to the presence of dissolved organic matter and ions, carbamazepine degradation in river water was slower than in clean water, both in the presence and absence of suspended particles, when the adsorption dosage was adjusted from 0 to 5 kGy.

Used electron beam irradiation to study the degradation of fluoxetine and discovered that a modest irradiation dosage of 0.5 kGy was enough to accomplish almost 90% elimination, despite partial mineralization (12.5 percent) at a comparable dose. The acute toxicity of Daphnia similes was related to residual levels of the parent chemical fluoxetine, rather than any by-products. Antibiotic resistance control in a wastewater treatment facility has been effective utilizing electron beam treatment (using a linear electron accelerator) [6].

Radiation has been described as a clean process since no extra chemicals are required to start the reaction, the energy cost is low, and the process may be carried out at different temperatures Aside from the degradation kinetics resulting from radiation-induced degradations, investigations should concentrate on radiolysis degradation products, mineralization, and toxicity, which have been mostly overlooked in the preceding research. In addition, at ecologically relevant concentrations, possible ionizing irradiations such as electron-beam radiation and gamma radiation should be studied.

The synergistic effect and the higher quantity of reactive species, which also causes greater mineralization, are responsible for the enhanced elimination of pharmaceuticals in hybrid systems compared to single AOP. APIs in actual or synthetic wastewaters are either treated sequentially or concurrently to optimize degradation efficiency [7] .

Combinations of AOPs, AOP selections, and treatment orders differ from research to study, and there is no clear consensus on this point. Although significant TOC removal was found (60 percent for synthetic secondary effluent and 80 percent for distilled water) as compared to the single treatment, the research failed to support the treatment order, and it was suggested that both methods be investigated concurrently. Adityosulindro and colleagues used a combination of ultrasonic and Fenton to eliminate and improve TOC levels of ibuprofen in distilled water and municipal wastewater from a treatment facility. Sonolysis in combination with ozonation and photolysis has also been investigated. Although the removal % was improved, the applied ozone flow rate had a significant impact on the removal efficiency for both single APIs and combinations. Because of increased ozone mass transfer, combining ozonation with ultrasound improved API breakdown, although it was dependent on the hydrophobicity of the molecule [8].

By evaluating TOC levels, researchers examined the potential of sonolysis and photolysis Sono-photolysis removed 91 percent of TOC, compared to just 3 percent and 8 percent for sonolysis alone and photolysis (UV) alone, respectively. The need to enhance mineralization levels, which is difficult to accomplish with sonolysis alone, drives the demand for combining sonolysis with other AOPs Complete mineralization of amoxicillin and diclofenac was also enhanced by combining ozonation with TiO2 photocatalysis result for the breakdown of medicinal combinations using a combination of. In addition, as compared to ozonation alone, and offered improved TOC removal.

More study is being focused towards this field of research since the majority of hybrid and integrated methods outperform solo therapies .Although it is clear that different AOPs are effective in eliminating medicines, the majority of AOPs are considered to be costly. To address this shortcoming, combining advanced oxidation treatment with current conventional water treatment techniques has been proposed as a more cost-effective and efficient solution Coupling AOPs has been proven to enhance effluent quality prior to release into the environment, as shown by a recent research that showed “safer” effluent when ozone and sonolysis were combined for amoxicillin degradation in water [9] .

The sequence of the linked treatment was not stated or explained in the experimental part of the majority of the hybrid studies described above. Future research should give rationale for the use of various treatment combinations in the treatment of pharmaceutical wastewater. Although linked AOPs offer greater mineralization, research should be conducted to back up this claim by identifying intermediates to ensure that the coupled AOPeffluent has little or no environmental impact compared to solo AOPs [10].

3. CONCLUSION:

The treatment of pharmaceutical residues using a variety of AOPs is gaining popularity as a result of their effectiveness and/or efficiency. The most widely used electrochemical procedures

for the treatment of synthetic aqueous solutions containing pharmaceutical residues have been EAOPs, particularly those based on the electro generated Fenton's reagent, such as the EF, PEF, and SPEF processes. The Fenton's reaction between catholically electro generated H2O2 and added iron catalyst generates •OH in the bulk, giving these techniques a strong oxidation ability. The •OH radical allows for extremely rapid aromatic ring breakage as well as the gradual oxidation of certain aliphatic carboxylic acid by-products. However, summarizes the main benefits and disadvantages of electrochemical separation and degradation methods. Advantages of Technology Drawbacks Membrane-based methods Large-scale volume treatment Membrane prices are very high.

Removal of huge amounts of organic debris and salts cleaning and maintenance issues are a common occurrence (membrane fouling) moderately fast only pollution separation is possible. Work in batch mode most of the time. Electrocoagulation Large volumes and heavy organic loading need special treatment. Electrode deterioration necessitates replacement. Removal of a significant proportion of colloidal and ionic materials Sludge production is a process that involves the production of sludge. Particles are electroplated by H2 bubbles. Only pollution separation is possible. Electrodes are inexpensive. It's possible to run in a nonstop mode. Moderately fast Micro-electrolysis on the inside Large-scale volume treatment Iron and carbon granules in large amounts are needed. Removal of large amounts of colloidal and ionic materials Sludge production is a process that involves the production of sludge. Electrodes are not required (no electrical cost) Removal is rather sluggish.

It's possible to run in a nonstop mode. Only pollution separation is possible. Oxidation via electrochemistry Large-scale volume treatment (need of large anodes or cell stacks) Fouling of the electrodes Degradation of organic materials accounts for a significant proportion of the total. Anodes with a high O2-overpotential cost a lot of money. There are no pH limitations. Keep an eye out for halogenated by-products. Work in batch mode most of the time. Processes based on Fenton Large-scale volume treatment (need of large electrodes or cell stacks) pH control (pH around 3.0) and neutralization is required. After treatment (sludge production), organic matter degrades quickly and in high percentages (more remarkable under sunlight irradiation) Keep an eye out for halogenated by-products.

H2O2 cathodic generation Work in batch mode most of the time. Photoelectrocatalysis a little amount of bias potential is needed. UV light use has a high expense. Degradation of organic materials is slow yet significant. Photoactive reactor in a certain setupPhotocatalyst that has been immobilized (no need for separating anodes or quartz glass filtering after treatment) Keep an eye out for halogenated by-products. Work in batch mode most of the time. Plasma that isn't heated large quantities of reactive oxygen species (ROS) is produced. Electricity is expensive. High productivity (low heat losses) Small-volume processing Keep an eye out for halogenated by-products.

Work in batch mode most of the time. Environment International 40 •OH, certain refractory carboxylic acids need UV radiation from commercial lamps or sunshine, as well as high oxidation power anodes. Electrochemical oxidation using "non active" anodes such as BDD and electrocoagulation, on the other hand, has been used to treat actual hospital and pharmaceutical wastewaters. Because these wastewaters often include Cl ion, the electro-oxidation process generally involves active chlorine species, making the use of "active" anodes like Ti/RuO2 intriguing. For the treatment of these contaminants, electrochemical separation methods and PEC have been less well documented, and additional study is needed to get a complete knowledge.

THE CONCEPT OF OTHER COMPREHENSIVE INCOME, ITS ESSENCE AND COMPOSITION, REFLECTION IN THE FINANCIAL STATEMENTS

Eshpulatova Zaynab Baratovna*

*Assistant,
Department of Accounting and Auditing,
Applicant for the Samarkand Institute of Economics and Service,
UZBEKISTAN

ABSTRACT

The implementation of international financial reporting standards (IFRS) in our country is one of the important issues on the agenda. One of the most important tasks of the country today is the application of international practice in the accounting system for the recognition of income and expenses, which are the main indicators of financial accounting. This article describes and discloses the concept of accounting for the concept of other comprehensive income, its essence and composition, reflection in the financial statements in accordance with international standards, the importance in the accounting system. Studying and improving the methodological side of this process today also remains one of the most important issues. This article also discusses income that is included in the income statements, such as the definition, composition, recognition, measurement and composition of the financial statements of other comprehensive income by type.

KEYWORDS:*Income, Income, Other Comprehensive Income, Expense, Reserve, Reclassification, Adjustment, International Financial Reporting Standards, Royalties, Dividends, Rent, Interest, Profit From Financial Activities.*

INTRODUCTION

In the new Uzbekistan, intensive work is underway to reform accounting. An important regulatory document in this regard is the Resolution of the President of the Republic of Uzbekistan dated February 24, 2020 RP-4611 "On additional measures for the transition to international financial reporting standards" [1]. International Financial Reporting Standards (IFRS) is a set of documents developed by international professional organizations. Their study and implementation requires a deep analysis of each standard and the development of guidelines for their application.

Therefore, the organization of settlements in accordance with the requirements of this standard, the presentation of transparent information on income and profit in financial statements, to international investors by means understandable to them, that is, the most proven and effective

methods and technologies, recognition and assessment criteria, the introduction of a methodology for providing reliable, consistent and Comparable financial information on the company's earnings, profits, distribution and profit share using international rules and principles is an urgent task for all countries, especially those that apply IFRS for the first time.

In our country, certain results have been achieved in harmonizing the accounting of income and profit with IFRS. In particular, in accordance with NAS No. 2 “Income from operating activities” and the Regulation “On the structure of expenses and the procedure for determining financial results”, a procedure for obtaining income and financial results has been developed in accordance with international standards, since 2021, on a voluntary basis, procedures have been introduced for the preparation, international audit and publication of financial statements in accordance with IFRS for joint-stock companies, banks, insurance companies, state-owned enterprises and other enterprises.However, these achievements do not mean that the country has made a decision on a full transition to IFRS. At the same time, it should be noted that based on the strategic objectives, there are a number of issues that need to be addressed in order to improve the accounting of income and profits in accordance with the requirements of international investors. These include the recognition and widespread implementation of IFRS on income, abandoning old methods and techniques, using modern conditions for generating income, developing, measuring and reporting income, using the most advanced recognition methods, recognizing distributed profits among foreign investors and improving accounting methodology. content and structure of the statement of financial results, recognition and reflection of other comprehensive income, improvement of the content of the accounts of income and profit accounting, harmonization of the formation of final financial results and accounting in accordance with international standards, achieving transparency and comparability of the report, transformation, transformation and consolidation issues and drawing up reports. To ensure the effective implementation of these tasks, scientific research is needed to radically improve the methodology for recording income and profits and reporting financial results in accordance with the requirements of international standards for foreign investors and other information users.

The transition to international standards requires the division of income into two categories: 1. Income reflected in the income statement; 2. Other income received that is not reflected in the income statement.

In the paragraphs above, we have discussed the issues of recognition, measurement and accounting of income, which are mainly reflected in the income statement. In this section, we explore the definition, composition, recognition, measurement and presentation of other comprehensive income that is not recognized in the income statement.

S.N. Tashnazarov calls other consolidated income other comprehensive income, defining it as follows: “Other comprehensive income includes items of income and expense (including reclassification adjustments) that are not recognized in profit or loss, they are required and allowed in other IFRSs”[1].

In the ASSA graduate book in finance and business administration “Other gross income - including income and expenses that are not recognized in profit or loss (that is, they are recognized in reserves and not in profit or loss for the period)”.[2]

Irina Zavalishina notes that other comprehensive income is reflected in the statement of changes in equity: “Other comprehensive income (OCI) are items of income and expense that were not previously recognized in the income statement, but are impartially reflected in the statement of changes in equity"[3].

Elena Vakaryuk, professor at ASSA, said: "Changes related to other non-core activities of the company, which arise as a result of different revaluation of certain items in accordance with the requirements of various IFRSs, are reflected in other general income"[4].

Emphasizes the importance of the approach to recognizing other generalized income in sources. The main criterion: "There are several points of view, the most common of which is that all other unrealized income includes all unrealized income and expenses, that is, income that is not ready to cash flow at any time during the company's activities. For example, a revaluation of a manufacturing building (that is, an item of property, plant and equipment) is unlikely to occur in the next period that is expected in the course of the company's operations. The revaluation of such instruments represents unrealized gains that are recognized in other comprehensive income. On the other hand, the change in the fair value of a leased building (classified as investment property) represents realized income which is recognized in the income statement. Why?, Because, this is due to the fact that investment property can be sold at any time, depending on its accuracy, when the company decides that the investment objectives have been achieved and the building can be sold. investment property is likely to become cash flow for the foreseeable future"[5].

The definitions given in the above regulatory documents, as well as by scientists, have basically the same meaning and disclose the characteristics of other generalized income. Summarizing these definitions, we define other generalized income as follows: "**Other comprehensive income** is a part of an enterprise's comprehensive income, including items of income and expense, unrealized income that is not reflected in profit or loss is reflected in the statement of changes in equity, and their composition and accounting is provided and allowed in a separate IFRS".

A number of other characteristics of generalized income follow from this definition. **First,** there are income and expenses. However, it is not taken into account when calculating profit and loss, including net profit. Other comprehensive income is an integral part of the company's total comprehensive income. It can also be expressed by the following formula:

$$\text{Total comprehensive income} == \text{Profit and loss} + \text{Other comprehensive income} (\mathbf{1.1})$$

IFRS does not draw a dividing line between the components of this comprehensive income. There is one rule in the standards. All income and expenses are recognized only in profit or loss, except for items specified in separate IFRS. The items that are defined on a case-by-case basis in these separate standards are referred to as other comprehensive income. In our practice, the concept of other comprehensive income has not been applied. Today, for our country, which is moving to international standards, it is important to define, recognize and reflect in the structure other aggregate incomes.

Second, items included in other comprehensive income represent unrealized income. For example, as in the example above, income from revaluation of property, plant and equipment is unrealized income. Revaluation of fixed assets increases their value, but does not yet imply sale. The company has no information or plans as to when it will sell these assets in the future.

Third, gains and losses are recognized in the statement of changes in equity under retained earnings, while other comprehensive gains are recorded in the accounts that record these gains in the statement of changes in equity or are included in other items of general income. in the manner prescribed by the accounting policy. Consequently, other total income is an element of private capital.

Fourth, other income information is extremely useful information for managers and other decision makers. Consequently, international standards require users of the information to provide detailed and reliable information about other comprehensive income.

Fifth, until now, in our practice, the concept of other aggregate income has not been used. In 2021, companies that are moving to international standards will definitely have to reflect in their reports. Given the importance of these indicators for enterprises operating on the basis of our national standards, we consider it appropriate to amend our national standards accordingly.

Now let's talk about the components of other comprehensive income. All of the above sources list the components listed in IFRS. Their constituent parts, the name of IFRS and their content are shown in Table 3.1 below.

TABLE 3.1COMPONENTS OF OTHER COMPREHENSIVE INCOME IN ACCORDANCE WITH IFRS

s/n	Other types of comprehensive income	IFRS	Content
1	Change in value growth from revaluation	IAS №16 “Fixed Assets” and IAS №38 “Intangible Assets”	The increase in the value from the revaluation of "Fixed assets" and "Intangible assets" is carried out under the item "Revaluation reserve" of private equity.
2	Actuarial gains and losses on retirement benefit plans recognized in accordance with IAS №19 “Employee Incentives”;	IAS №19 “Employee Incentives”	Actuarial gains and losses are changes in the present value of fixed liabilities that result from: (a) adjustments based on experience (the results of differences between initial actuarial estimates for future events and actual events); (b) changes in actuarial tolerances
3	Profits and losses from the financial statements of the foreign division;	IAS №21 "The Effects of Currency Exchange Rate Fluctuations"	If exchange differences arise in the consolidated financial statements of the reporting entity in accordance with paragraph 31 of the standard, they are recognized in other consolidated income and accumulated as a separate component of equity until the foreign operation leaves.
4	Gains and losses on the revaluation of financial assets available for sale	IAS №39 “Financial Instruments: Recognition and Measurement”	Gains and losses on financial assets (equity instruments) at fair value through other comprehensive income. If an entity invests in securities to generate long-term dividend income and does not sell them when the market price rises, gains from changes in the fair value of financial assets are recognized in other comprehensive income.
5	Effective money planning results	IAS №39 “Financial Instruments: Recognition and Measurement”	Planning efficiency is the extent to which a change in the fair value or cash flows of a planning item associated with the planning risk is offset by a change in the fair value or cash flows of the planning instrument.

Other aggregates fall into two categories in the income classification. The first category is items that cannot be reclassified in the income statement. Other comprehensive income in this category will be reclassified to profit or loss when certain comprehensive income arises under certain conditions. The second category is items that can be reclassified in the income statement. Other items of income earned in this category are not reclassified to profit or loss under any circumstances. They accumulate as an element of private capital. In this regard, the structure of

other comprehensive income in the "Statement of Profit and Loss and Other Comprehensive Income" format, proposed in the materials prepared by the PwC Academy in 2020, is as follows (Table 3.2):

TABLE 3.2FORMAT OF THE CONSOLIDATED STATEMENT OF PROFIT OR LOSS AND OTHER COMPREHENSIVE INCOME OF ABC FOR THE YEAR ENDED DECEMBER 31, 2013 (ONLY OTHER PART OF COMPREHENSIVE INCOME)[6]

	2013	**2012**
Other comprehensive income: **Components that cannot be reclassified in the income statement.**		
Revaluation of fixed assets	**X**	**X**
Gains (losses) on investments in equity instruments carried at fair value through other comprehensive income at the option of the Company	**X**	**X**
Actuarial gains (losses) for defined benefit plans	**X**	**X**
The contribution of like-minded people to the increase in the value of the property	**X**	**X**
Changes in the fair value of financial liabilities associated with their credit risks	**X**	**X**
Income tax applicable to components that cannot be reclassified	**(X)**	**(X)**
Components that can be reclassified in the income statement		
Gains (losses) on financial assets (equity instruments) measured at fair value through other comprehensive income	**X/(X)**	**X/(X)**
Exchange rate differences when translating foreign subsidiaries	**X**	**X**
Effective money planning results	**X**	**X**
Income tax applied to the reclassified components	**X**	**X**
Total other comprehensive income after tax	**X**	**X**

This format is a proposed format that companies can develop in their accounting policies in accordance with IAS formats.

In our opinion, it is advisable to open accounts designed to reflect other total income in the current chart of accounts. This is due to the fact that, in accordance with the requirements of international standards, any result that is reflected in the increase in the assets of private equity holders, in addition to adding additional private capital, is income. Based on this view, other comprehensive income should first accumulate in accounts opened for other types of comprehensive income. At the end of the reporting period, these income accounts will need to be transferred to the corresponding private equity accounts. Since these are accounts after the final financial results, it is recommended to open account 10000 "Other income received":

TABLE 3.3WORKING ACCOUNTS, WHICH ARE PROPOSED TO BE INCLUDED IN THE CHART OF ACCOUNTS OF FINANCIAL AND ECONOMIC ACTIVITIES OF BUSINESS ENTITIES[7]

Account number	**Account name**
10010	Income from revaluation of property, plant and equipment and intangible assets (not a reclassified component)
10020	Gains and losses from the revaluation of financial assets
10021	Profit (loss) on financial assets (equity instruments) carried at fair value (reclassified component)
10022	Gains (losses) on investments in equity instruments carried at fair value (not a reclassified component)
10030	Actuarial gains (losses) for defined benefit plans (unclassified component)

10040	Contribution of the parent company to the increase in the value of the assets of the associates (non-reclassified component).
10050	Change in fair value of financial liabilities (non-reclassified component).
10060	Exchange differences arising on the translation of foreign subsidiaries (component that can be reclassified)
10070	Effective cash planning results (reclassified component)
10080	Income tax applicable to other comprehensive income
10081	Income tax applied to the reclassified components
10082	Income tax applicable to components that cannot be reclassified

Let us consider the application of these accounts and the methodological procedure for accounting for other generalized income on practical examples.

Example 1. The net profit of "Jambay Grain Products" JSC for the reporting year ended 2020 amounted to 238 785 141 thousand UZS, the cost of goods sold (goods, works, services) 200 606 212 thousand UZS, other (not related to ordinary activities) income 2 097 633 soums, operating (commercial) expenses 28 455 639 thousand soums, administrative expenses 844 746 thousand soums, non-operating expenses 12 450 thousand soums, interest income 14 037 thousand soums, profit (loss) from the disposal of financial assets at amortized cost 4 255 thousand soums, gain / loss from reclassification of financial assets from amortized cost through profit or loss to fair value for 2,400 thousand soums, impairment loss - 1,500,000 soums, impairment loss - 1,500 thousand soums, finance costs - 1,885,677,000 soums.

The authorized capital of the company is 248,420,000 soums, retained earnings - 150,448,500,000 soums. Reserve capital 58,425,123,000 soums.

In the reporting year, the following transactions took place on other gross profit: increase in the value from revaluation of fixed assets - 28,400 thousand, profit (loss) from financial assets measured at fair value at the company's option through other comprehensive income - 5,800,000 soums, fixed actuarial gain (losses) on pension plans with benefits (non-reclassified component) - 0, effective funds planning results - 0, contribution to the increase in the property value of associates - 0, exchange rate difference from translation of foreign subsidiaries - 0.

Based on the following information, it is required: 1. Preparation of a part of the income statement on total comprehensive income (profit and loss and other comprehensive income) for the reporting year ended December 31 of JSC. 2. To reflect other comprehensive income in accounting. 3. Prepare the second part of the statement of total comprehensive income; 4. Prepare a statement of changes in equity; 5. Prepare a section on private equity in the statement of financial position.

1. Based on the above data, we form the Profit and Loss section of the statement of total gross income (Table 3.4):

TABLE 3.4PART OF THE PROFIT AND LOSS IN THE STATEMENT OF "JAMBAY GRAIN" JSC ON COMPREHENSIVE GROSS INCOME FOR THE REPORTING YEAR ENDED DECEMBER 31, 2020[8]

Indicators	**Line code**	**Sum**
Profit and loss (thousand UZS):		
Revenue	010	238 785 141
Cost of sales	020	200 606 212
Gross profit (010-020)	030	**38 178 929**
Other income	040	2 097 633
Other expenses	050	12 450
Operating (trading) expenses	060	28 455 639

Administrative expenses	070	844 746
Operating profit (3+4-5-6-7) (030+040-050-060-070)	**080**	**10 963 727**
Interest income	090	14 037
Gain (loss) on disposal of financial assets at amortized cost	100	4 255
Gains / losses arising from the reclassification of financial assets at fair value at cost rather than amortized cost through profit or loss	110	2 400
Impairment loss	120	1 500
Finance costs	130	1 885 677
Profit and loss before tax (080+090+100+110-120-130)	**140**	**9 092 987**
Income tax	150	1 459 600
Profit from current activities (140-150)	**160**	**7 633 387**
Loss from discontinued operations for the year	170	-
Profit for the year (160-170)	**180**	**7 633 387**

2. At the next stage of calculations, we reflect other comprehensive income in the accounting accounts. For this we use the accounts suggested above. The essence of the methodological procedure we propose is that other comprehensive income is initially accumulated in the accounts intended for each of these incomes. At the end of the year, the balances in these accounts are transferred to the corresponding private equity reserve accounts. In the statement of private capital flows, we consider the most appropriate practice to open a column of reserves and other reserves to increase the value of fixed assets and intangible assets. Based on these rules, we make accounting entries in the following table (Table 3.5):

TABLE 3.5THE ORDER OF REFLECTION IN THE FINANCIAL STATEMENTS OF OTHER AGGREGATE PROFIT OF "JAMBAY" JSC FOR 2020 UNTIL DECEMBER 31[8]

s/n	**Contents of operation**	**Linking accounts**		**Sum**
		Debit	**Credit**	
1	Increase in value from revaluation of fixed assets	0110-0130	10010	28 400 000
2	Gains (losses) on financial assets measured at fair value at the company's option through other comprehensive income	0610 or other accounts related to financial assets	10021	5 800 000
3	Actuarial gains (losses) for defined benefit plans (unclassified component)	6990 "Accounts accounting for actuarial obligations"	10030	-
4	Effective money planning results	5110-5700	10070	-
5	The contribution of like-minded people to the increase in the value of the property	0610-1690	10040	-
6	Exchange rate differences from translation of foreign subsidiaries	5210	10060	-

7	At the end of the year, when other comprehensive income is transferred to reserves:	10010	8510	28 400 000
	Increase in the value of property, plant and equipment.	10021	8540 Other reserves	5 800 000
	Increase in the value of financial assets.	10030	8540	-
	Actuarial advantages and disadvantages. Money planning.	10070	8540	-
	Employee contributions to property value.	10040	8540	-
	Exchange rate difference from translation of foreign subsidiaries.	10060	8540	-

The methodological procedure suggested in this table has several advantages. **First,** changes in other comprehensive income during the year are first accumulated in the accounts in which this income is recorded, and then the final result is transferred to reserve capital. This, in turn, reduces the income from a previous increase in property, plant and equipment during the year as a result, for example, of a loss in the value of property, plant and equipment transferred to the corresponding other comprehensive income account. **Second,** the data in the other comprehensive income accounts make it easier to aggregate the data when completing the Other comprehensive income section of the statement of total comprehensive income. It allows you to receive data for replenishment not from the reserve capital, but from the data in the accounts for these purposes. This methodological procedure also meets the requirements of international standards and is distinguished by its effectiveness.

3. Now, based on the information in the other comprehensive income accounts, we will complete the "Other comprehensive income" section in the statement of comprehensive income. To do this, we enter the data in the format recommended by PwC Academy above and formulate the corresponding report indicators (Table 3.6).

TABLE 3.6PART OF THE OTHER COMPREHENSIVE INCOME OF JSC "JAMBOY GRAIN PRODUCTS" FROM THE TOTAL COMPREHENSIVE INCOME FOR THE YEAR ENDED 31 DECEMBER 2020 (OTHER PART OF COMPREHENSIVE INCOME ONLY)[8]

	Line code	**Sum**
Other comprehensive income: components that cannot be reclassified in the income statement		
Revaluation of fixed assets	190	28400000
Gains (losses) on investments in equity instruments carried at fair value through other comprehensive income at the option of the Company	200	-
Actuarial gains (losses) for defined benefit plans	210	-
The contribution of like-minded people to the increase in the value of the property	220	-
Changes in the fair value of financial liabilities associated with their credit risks	230	-
Income tax applicable to components that cannot be reclassified	240	-
Components that can be reclassified in the income statement		
Gains (losses) on financial assets (equity instruments) measured at fair value through other comprehensive income	250	5 800 000
Exchange rate differences when translating foreign subsidiaries	260	-

Effective money planning results	270	-
Income tax applied to the reclassified components	280	-
Total other gross profit after tax (190+200+210+220+230+240+250+260+270+280)	**290**	34 200 000
Total comprehensive income (180+290)	**300**	**41 833 387**
Profit: **Controlled shareholders**	**310**	**41 833 387**
Uncontrolled participation	**320**	**-**

This statement is a continuation of the statement of comprehensive gross income above. The report shows that the joint-stock company received income only on two items of other comprehensive income. No operations were carried out for the rest of the items. Total comprehensive gross income consists of the enterprise's profit and loss and other comprehensive income. There is no uncontrolled participation in the company. Therefore, all comprehensive income is attributable to controlled shareholders.

4. At the next stage of calculations, it is necessary to prepare a report on the change in private capital. Its composition and content are as follows (table 3.7).

TABLE 3.7"JAMBAY GRAIN PRODUCTS" JSC PRIVATE EQUITY REPORT 2020 ENDED DECEMBER 31

	Authorized capital	**Share capital**	**Undestributed profits**	**Vehicle revaluation reserve**	**Other reserves**	**Total capital**
Incoming balance	248 420 000	6 518 000	150 448 500	58 425 123		463 811 623
Net profit			7 633 387			7 633 387
Dividend			(4 580 032)			(4 580 032)
Other comprehensive income				28 400 000	5 800 000	34 200 000
Outgoing balance	248 420 000	6 518 000	153 501 855	86 825 123	5 800 000	501 064 978

The advantage of this report is that it shows an increase in retained earnings compared to net income. The net profit indicator is taken from line 180 of the profit and loss section of the statement of comprehensive income. Dividends are paid out of net income, which results in a decrease in net income. The rest is reflected in an increase in retained earnings. There are two columns for capital reserve. One of them is the reserve for property, plant and equipment, the reserve for revaluation of intangible assets, and the other is the reserve for the remaining items of other comprehensive income. You can open a separate column for each item of other comprehensive income, but since there are many other items of total income, the report format may be larger than normal, which makes it inconvenient to use.

4. The data of the statement of changes in private capital must correspond to the data of the balance sheet (table 3.8).

TABLE 3.8REFLECTION OF ITEMS OF DIRECT INVESTMENT IN THE FINANCIAL STATEMENTS OF "JAMBAY GRAIN PRODUCTS" JSC FOR 2020, WHICH ENDS ON DECEMBER 31

Reporting elements	**Sum**
Capital and reserves: Share capital	248 420 000
Share capital	6 518 000
Undestributed profits	153 501 855
Revaluation reserve for property, plant and equipment	86 825 123
Other reserves	5 800 000
General	**501 064 978**

These reported data should be consistent with the reported data on the movement of direct investment. The information in the report describes the financial condition of the company.
Based on the above research, the recognition, measurement and reporting of other comprehensive income can be divided into the following stages:

The first step is the recognition of other generalized income, their classification into items that can and cannot be reclassified into profit or loss;

The second step is to reflect other comprehensive income in the accounting records;

The third step is to develop a format for the part of the income statement in the general income statement and fill it out based on the accounting data;

The fourth step is to develop a format for the other part of the consolidated income in the statement of comprehensive income and fill it out based on the accounting data;

The fifth step is to prepare a statement of changes in equity based on the data in the statement of comprehensive income;

The sixth step is to compare the financial statement and the private equity statement data.

Based on the study of other comprehensive income, the following conclusions can be drawn:

1. Other comprehensive income was described based on a study of international standards and industry literature. These gains represent unrealized gains that are not recognized in the income statement, which are recognized in the statement of comprehensive income, and the final financial results are reflected in the statement of changes in equity. Accounting for other comprehensive income is provided for and permitted by separate IFRSs. The study identified five characteristics of other comprehensive income.

2. The components of other comprehensive income are given, their definitions, for the purpose of classification, are divided into two categories. The first category is components that cannot be reclassified in the income statement. The second category is components that can be reclassified in the income statement. The constituent parts of these components have been identified in accordance with international standards.

3. To reflect other comprehensive income in accounting, a chart of accounts was proposed for opening accounting accounts for each item of other comprehensive income, and their application was demonstrated using practical examples.

4. Based on practical examples, methodological rules have been developed for the application of the methodological procedure for drawing up the profitable and unprofitable part of the statement of other comprehensive gross income for the reporting year, as well as other parts of

the total income at domestic enterprises. A six-step methodical procedure for reflecting other incomes in accounts and reports is proposed.

5. The methodological aspects of reflecting other total income of joint-stock companies in the statement of changes in private capital and financial statements have been improved.

This methodological procedure serves to generate useful information for users of information that accurately reflects other total income in the accounts and reports.

ARTISTIC DESCRIPTION OF THE HERO'S SPIRIT IN ERKIN VOKHIDOV'S EPIC "NIDO"

Shahlo Hojieva*

*Associate Professor,
Doctor of Philosophy in Philology,
National University of UZBEKISTAN
Email id: sh.hojiyeva@mail.ru

ABSTRACT

In this article, the author tries to study the work of Erkin Vahidov. The author analyzes the artistic significance of Erkin Vahidov's epic "Nido". Erkin Vahidov's wide range of creative heritage, high art, unique style of expression have a special place in the development of Uzbek literature in the second half of the XX century - early XXI century. The poet's delicate lyrical poems, humor, which embodies the desire to see the native people without flaws, epics with deep layers of meaning and a unique world of images are rare examples of our national literature. In his works, the artist sang about the pain of the people, devoted all his inspiration and energy to the deep revelation of the human psyche, the skillful depiction of high ideals.

KEYWORDS:*The Epic "Nido", the War Years, Human Destiny, the Human Psyche, Artistic Methods.*

INTRODUCTION

Erkin Vahidov's wide range of creative heritage, high art, unique style of expression have a special place in the development of Uzbek literature in the second half of the XX century - early XXI century. The poet's delicate lyrical poems, humor, which embodies the desire to see the native people without flaws, epics with deep layers of meaning and a unique world of images are rare examples of our national literature. In his works, the artist sang about the pain of the people, devoted all his inspiration and energy to the deep revelation of the human psyche, the skillful depiction of high ideals.

The poet wrote about ten epics. His epics "Tashkent sadosi", "Quyosh maskani", "Buyuk hayot tongi", "Charog'bon", "Baxmal", "Palatkada yozilgan doston", "Nido", "Ruhlar isyoni", "Istanbul tragedy" are high examples of this genre. in terms of It is known that the epics "Nido", "Ruhlar isyoni" and "Istanbul fojeasi", which made a worthy contribution to the development of modern Uzbek epics, brought fame, especially to the poet. Although Nido was written in 1964, it has not lost its value. The epic has taken root in the hearts of our people and is still loved and read.

The play depicts the wounds of the Second World War in the hearts of our people. In the “Dedication” part of the epic, the artist depicts the inner feelings of the protagonist, the feelings in his heart in an impressive style, artistically. In the preface of the work, the language of the “lonely monument” of the lyrical hero-victim of war is interpreted in a highly artistic way. By the phrase “From under Mother Earth”, the poet is referring to the flames of war. “Son!” The tragic effect of war on human life through the expression of the suffering of a child who has not uttered the word “Father” for twenty years, whose body is in agony, whose heart is burning with pain, who has no tears in his eyes, who feels the pain of a black bullet piercing his father's chest. deeply expressed.

The epic “Nido” is also significant in that it is based on a biographical interpretation. “First of all, this epic is distinguished by high art, sincerity, truthfulness, deep humanism,” writes literary scholar Umarali Normatov. - The epic is dedicated to war and the human problem. This problem, which has been repeatedly mentioned in the literature, is uniquely worked out in Erkin Vahidov's epic, and his personal involvement in the event has given a wonderful sincerity to the work. ”

While writing about the heavy steps in the play, the soil trembling from the impact of the boots, the poet asks the anguished questions: “Where are so many people going? Isn't that how far they go? ” At that moment, the protagonist suddenly sees his father among them:

Ana, ko’rayapsanmi?

Mening dadamlar!

Dada!!!

Ovozim hech chiqmaydi biroq.

Yuguraman - ortga ketar qadamlar.

Yig’layman – ko’zimga kelmaydi namlar,

Murg’ak vujudimda faqat zo’r titroq!

Erkin Vahidov is a master of the image of the soul. Through words, the poet is able to express emotion with all its complexity as clearly as a skilled artist. The lyrical protagonist is the child's “Father!” the fact that he does not make a sound when he calls, that he does not step back when he runs, that he does not get tears in his eyes when he cries, that he does not tremble in his body - every word in these lines has a universal meaning. Everything serves to depict the mood of the hero in bright colors. The combination of creative intent and image at this level confirms the words of the literary critic Ibrahim Gafurov: He seeks the logic of every event, focusing all his attention on the logic of the events. He is very strong in logic.

These verses have a lightning effect on the heart of the reader. As he reads the epic, he deeply feels the fiery rage of the protagonist. This is: “Literary creation is always a journey into the world of words. The Creator sees the Word as a living soul and speaks with the Word. I want what I have written to be a live conversation in such a lively language, ”said Erkin Vahidov.

In the epic, the image of the hero's psyche is also impressively expressed through the mother-child dialogue. The mother's words of encouragement to her child resonate in the student's heart:

Ellarning erk degan

Sof tilagi deb,

Jahonning nurafshon

Kelajagi deb,

Ofat solmasin deb

Olamga qotil,

Otang uzoq yurtda

Jang qilayotir.

While the poet describes the “bright future” in the above verses, it instills in the child's heart a confidence in the future, a love of life and, at the same time, a sense of pride in his fighting father. Onaizor's words that these days will surely pass, that human wounds will end, that the world will become a world without war, but that the sorrows, stains, and heartaches of a terrible war will remain, are in harmony with the author's dreams.

The story of writing a letter to the father of a child in the epic, Rustam aka, who has no legs, Khol aka, who could not embrace his son because he had one arm left in the war, is the curse of Talat’s inability to come to school because of his father’s death. The storms in the heart of the protagonist of the epic - all confirm how skillful the poet is in the depiction of the soul. In these images, the psyche of a child with anxious eyes waiting for a letter from his father is depicted so vividly and emotionally that the pain in them burns in the heart:

Hijron kechalari g'oyatda uzun,

Ayriliq yo'llari olis nihoyat.

Kuchaga chiqaman yuz bora har kun,

Ko'zlarim nigoron,

Kelarmikan xat?

The poet's personality is the image of the poet's personality, which is full of anguish and sincerity: is proof that he was able to describe the psyche of the nation through his psyche.

The fate of four soldiers who fought valiantly against an entire regiment; in this battle between danger and courage, evil and justice, the lead in their chests, the resting like an innocent baby in the mother's womb after a heavy night's battle, is a poetic depiction of the reality that underlies the plot of the epic. Through the art of diagnosis, the poet depicts this event, which is associated with the tragic fate of human society, in harmony with the image of the landscape. The four heroes wept uncontrollably this morning, the river cried with its head on the shore, the white, fluffy clouds shattered, the sun's rays shed tears this morning - all this served as a perfect poetic depiction of the hero's psyche. The protagonist:

O'rmonlar shovillagan

Olis yurtda xali ham

Nomsiz tepalik uzra

Uxlab yotibdi otam.

The cry of is interpreted in proportion to the mourning of Mother Nature.

The image of Mother Earth groaning from the wounds of the sick, her heart breaking from the horrors of the atomic umbrellas, and calling with a fiery sigh in her chest, is in harmony with the cry in the psyche of the protagonist. Now it is the great responsibility of modern man to lead this troubled world, this troubled world, from storms and sunny roads to a brighter future. That's what the poet means!

The story ends with the following lines:

Avlodlar uchun ham

Qutlug' bo'lur albat

Yer uzra to'kilgan ko'z yosh, qon va ter.

Bepoyon kenglikda

Charx uradi abad

Ulkan yurak shaklidagi Yer ...

It is no coincidence that the image of the earth is likened to the heart. Because Erkin Vahidov imagines Mother Earth as a living being. It encourages mankind to live in peace in the bosom of this Mother. So that mothers do not lose their beloved spouse, children's valine - father! So that mankind does not lose humanity to the box of lust! After all, all humanity is the children of this heart-shaped Mother Earth.

In short, Erkin Vahidov, through the depiction of the heroic spirit in the epic, highly artistic interpretation of the universal problem that the preservation of the peace of the Mother Earth, the peaceful coexistence of the children of Adam is the main condition for achieving a bright future.

ABSTRACT

This paper looks at the current practices and future possibilities of using data mining methods to classify medical data. It focuses on the most important advanced classification methods for improving classification accuracy. Previous research has produced literature on the categorization of medical data using data mining methods. Data mining methods are highly successful for the job of categorization, according to substantial literature research. This study compared and contrasted the present state of medical data categorization. The study's results revealed that the current categorization of medical data might be enhanced further. Nonetheless, additional study is needed to determine and eliminate ambiguities in categorization in order to improve accuracy.

KEYWORDS:*Bayesian Network, Decision Tree, Diagnosis, Multilayer Perceptron, Support Vector Machine.*

21. INTRODUCTION

Marketing, customer relationship management, engineering, and medical analysis, expert prediction, web mining, and mobile computing are just a few of the areas where data mining has been utilized [1]. Data mining has recently been used to effectively identify healthcare fraud and abuse situations. Clinical choices are often made based on physicians' intuition and experience rather than the database's knowledge-rich data. This approach leads to unfavorable biases, mistakes, and high medical expenditures, all of which have an impact on the quality of care given to patients. This proposal has promise since data modeling and analysis techniques, such as data mining, have the ability to create a knowledge-rich environment that may enhance the quality of healthcare choices considerably [2]. Successful data mining applications have given the incentive for all parties engaged in healthcare-related businesses to fully use them, as they have recognized that data mining is critical in the collection of important information for all sectors concerned.

Healthcare insurers are more able to detect fraud and abuse, health managers are better able to make better choices, particularly when it comes to customer management, and healthcare practitioners are better able to provide better services and treatments [3]. Traditional techniques cannot handle and evaluate the massive quantities of data produced by healthcare transactions because they are too complicated and voluminous. By finding patterns and trends in huge quantities of complicated data, data mining may help people make better decisions. As financial constraints have increased the need for healthcare organizations to make choices based on clinical and financial data, such analysis has become more important. While maintaining a high level of care, data mining insights may impact cost, revenue, and operational efficiency. Data-mining-enabled healthcare companies are better positioned to fulfill their long-term requirements.

Computers and their peripherals have become cheaper and more widely accessible in recent years, and sophisticated data mining methods have emerged in tandem with the development of information technology. Traditional and more current advanced classification algorithms are included into these new generation data mining methods. Both classification methods are used to handle multidimensional datasets, user inference and prior knowledge, web data, erroneous data points that induce over fitting of models, human ability enhancement, noisy dataset cleaning, multimedia dataset mining, and incremental datasets. For all of the databases described above, interdisciplinary data mining methods and methodologies may be utilized to predict the effect and find significant connections in the data with the goal of extracting valuable information for knowledge creation.

To apply data mining algorithms to medical data, researchers must have a thorough understanding of the many types of data mining algorithms and their purposes. The two types of data mining techniques are descriptive (or unsupervised learning) and predictive (or supervised learning) [4]. Descriptive data mining classifies data by identifying item similarities (or records) and discovering previously undiscovered patterns or connections in the data, allowing users to recognize a large data set. Descriptive data mining is a research method. Clustering, association, summarization, and sequence finding are all part of it [5]. Predicting rules (also known as classification/prediction models) from (training) data are used to unpredicted/unclassified data in prediction data mining, which includes classification, regression, time series analysis, and prediction.

Three of the most often used data mining algorithms (classification, clustering, and association) are described here, along with recommendations for their usage, to help academics understand the significance of data mining and the use of data mining methods. As a result, a number of models have been fitted to the data in attempt to uncover hidden patterns. In this model, the method that produces the most accurate output and relationships pattern in the observed datasets is deemed the most efficient. This method accomplishes the goal of data mining. Classification, regression, clustering, finding association rules, and sequence analysis are all model functions used in current data mining techniques. However, as data mining becomes more popular, the task becomes more difficult. Soft computing has emerged as one of the promising data mining techniques in this field for dealing with these issues without utilizing conventional statistical approaches. For conventional software and hardware, digital medical data is not only massive in size, but also complicated in form. Traditional systems' inability to handle large datasets is due to a number of reasons, including:

- A wide range of organized and unstructured data, such as handwritten doctor notes, medical records, medical diagnostic pictures (MRI, CT), and radiographic films
- The presence of noisy, heterogeneous, complicated, longitudinal, varied, and big datasets in healthcare informatics.

- The need to improve medical problems such as quality of treatment, sharing, data security, and cost reduction, which are not well handled in conventional systems

As a result, solutions are required to handle and analyze such complex, varied, and large datasets in a reasonable amount of time and storage capacity in order to improve insight and decision-making. As a result, the purpose of this article is to provide an overview of the current and most often used techniques for categorizing medical data. Existing data mining-based methods to classification of medical records are being updated by emphasizing the various categorization algorithms for clinical imaging applications. There are three parts to this study. The second section contains a discussion that discusses data mining categorization, a comparative study of data mining methods, and the findings or outcomes. In addition, Section 3 of the article concludes with a conclusion.

22. DISCUSSION

22.1. Classification in Data Mining:

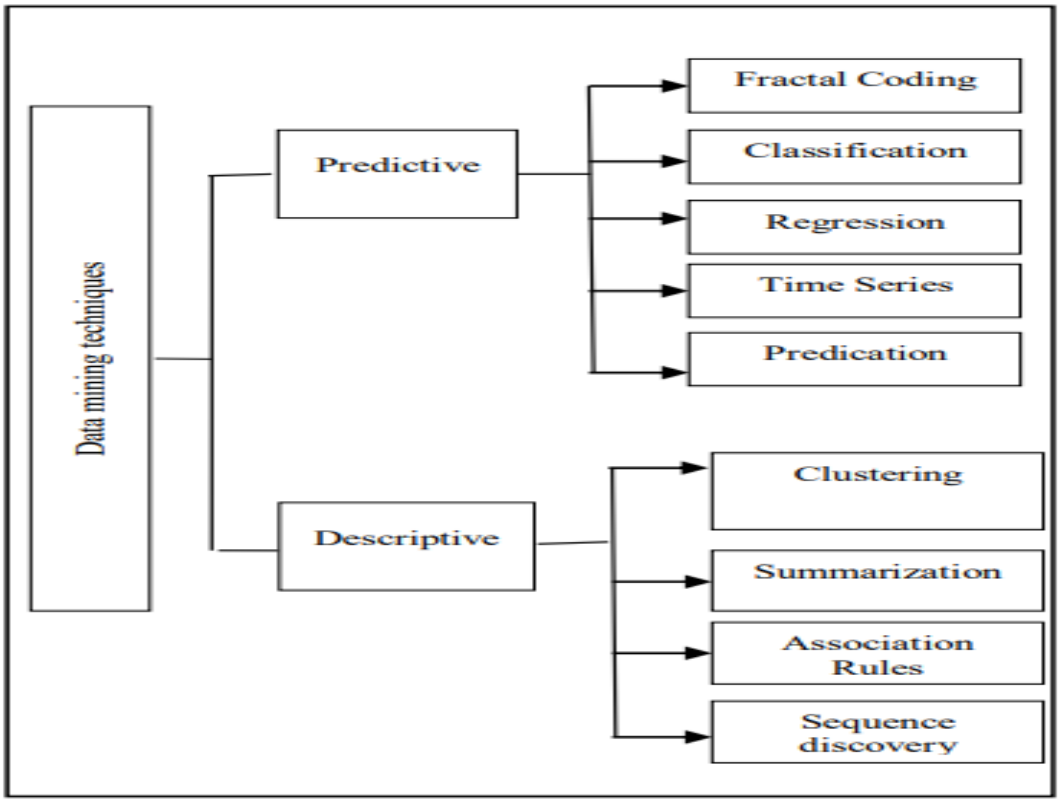

Fig. 1. Data Mining Techniques [4]

Categorization is a technique used in data mining to predict the memberships of a collection of data examples. To identify data linkages in large datasets, this method employs sophisticated data analysis. Medical databases provide difficulties for pattern extortion because to their complicated characteristics. Data mining techniques may be classified into two types: statistical and machine learning algorithms. Data mining methods are divided into descriptive and predictive categories as shown in Fig. 1. Descriptive mining tasks reveal the database's general data characteristics. Inference is performed on the data for predictions in predictive mining jobs, where forecasts are produced on explicit values based on patterns discovered by previous outcomes. Descriptive data mining offers features and descriptions for the data collection without having a specified goal.

Because: a) it is user-friendly and prediction is based on past circumstances; b) it operates by learning from past data; c) data from multiple resources is managed and only required data is

extracted; and d) models are easily updated by relearning, past information, and changes in trends, data mining techniques are effective and predictive for future patterns. This is what makes it dependable and useful in the classification of medical images. The three learning strategies in data mining algorithms are supervised (the technique performs with a number of instances with labeled data whose values are nominal in classification tasks, or numerical in regression tasks), unsupervised (the dataset contains unknown labels, and the algorithmic program aims at grouping examples based on the similarity of their attribute values, classifying a clustering task), and unsupervised (the dataset contains unknown labels, and the algorithmic program aims at grouping examples based on the similarity of their attribute values, characterizing a cluster [6].

22.2. Comparative Analysis of Data Mining Techniques:

Although the results of classification algorithms are impressive, none are yet varied and flexible enough to be widely recognized in the medical data classification field. In medical data, categorical variables may be helpful for making choices and generalizing information. Categorical data (e.g., disease and non-disease classifications) is useful for data mining techniques and also simple to extract medical data. Table 1 shows a short overview of data mining methods.

TABLE 1. DATA MINING TECHNIQUES REPRESENTATION [7]**.**

Approach	Representation	Pattern Recognition Models Recognition Function	Error Estimation
Template Matching	Sample, pixels, curves	Correlation, distance measurement	Classification error
Statitical	Featuers	Discriminatio n function	Classification error
Neural networks	Samples, voxel pixels, featuers	Network function	Mean square error

With the development of data mining for illness diagnosis and prediction, a large number of efforts for a range of medical picture classifications have been suggested [8], [9]. However, the many assumptions and hypotheses used in these techniques vary significantly. The section examines the rapidly growing corpus of work on the development and use of classification techniques to fundamentally important issues in medical image categorization. Meanwhile, classification researchers depend largely on stored data archives like the UCI repository to perform comparison studies, which enables novel algorithm concepts to be tested on established issues. Table 2 shows an overview of data mining methods. Data mining methods are used in mining medical data, and include association rule mining for identifying common patterns, prediction, classification, and clustering, which is a new use in the medical sector [10]. To date, many studies have been conducted, and intelligence and decision support systems have been created to improve illness detection and prediction, particularly in the areas of heart disease, lung cancer, and remote health monitoring.

The purpose of this section of the paper is to highlight the needs of the healthcare sector as well as possible solutions. Here are some recommendations for using various data mining techniques: Prior to using the classification method, it is essential to identify the superfluous characteristics that obstruct the processing job. They not only create noise and disrupt the process, but they also have an impact on the performance of the classifier. Statistical techniques are used to identify

them. The feature selection techniques, on the other hand, are used to pick functional characteristics in order to enhance the classification model's accuracy and success. As a consequence, the researchers discovered that no one classifier produces the optimal results for each dataset. Each dataset is divided into two sections – training and testing – to evaluate the performance of classifiers. A classifier is selected based on its performance in comparison to other available classifiers, which is evaluated using a testing dataset. To guarantee correctness, the training and testing datasets are subjected to cross validation.

TABLE 2. SUMMARY OF DATA MINING TECHNIQUES

Data Mining Technique	Advantage	Disadvantage
SVM	• Better Accuracy as compare to other classifier. • Easily handle complex nonlinear data points. • Over fitting problem is not as much as other methods.	• Computationally expensive. • The selection of right kernel function. For every dataset different kernel function shows different results. • Training process take more time.
Decision Tree	• No requirements of domain prior knowledge in the construction of decision tree. • It minimizes the ambiguity of complicated decisions. • It is easy to interpret and it also handles both numerical and categorical data.	• It generates categorical output. • Performance of classifier depends upon the type of dataset.
ANN	• Easily identify complex relationships between dependent and independent variables. • Able to handle noisy data	• Local minima. • Over-fitting.
Bayesian Belief Network	• It makes computations process easier. • Have better speed and accuracy for huge datasets.	• It does not give accurate results in some cases where there exists dependency among variables.
K-NN	• It is easy to implement. • Training is done in faster manner	• It requires large storage space. • Sensitive to noise.

Classification rules are primarily concerned with determining the class of characteristics, but they do not consider the connections between them. While association is beneficial for detecting the connection or correlation between several characteristics and produces association rules, domain experts may utilize this information to eliminate unimportant association rules and examine just those that are relevant to making important decisions.

22.3. Findings:

According to Table 1, each data mining modality has its own set of features to deal with. Despite all attempts, there is currently no widely accepted technique for categorizing medical data. The most obvious reason is that in the medical field, very accurate data and a very low incidence of false negatives are needed. However, there are certain generic techniques that can be used with a wide range of data. Specialized techniques for specific applications that take into account previous knowledge may help obtain better results. Over the last three decades, medical data has progressed in the following three areas:

- The creation and use of sophisticated classification algorithms.
- Making use of a variety of characteristics.
- Medical data is included into categorization processes.

Nonetheless, there are obstacles. Data mining technique, user engagement, performance, and scalability are among them. Other concerns include the investigation of data mining applications and their societal consequences. As a result, deciding on a suitable strategy to a classification issue may be a tough decision. As a result, there's a chance that the present medical data

categorization jobs may be improved further. Because data mining methods for medical data categorization have yet to be thoroughly explored, there is a lot of room for further study and new avenues for future research.

23. CONCLUSION

It is noted in this paper that data mining methods have been used to classify medical data. Because there are so many records in this medical data domain, using data mining methods to aid in decision support and prediction in the area of healthcare to detect illnesses has become a need. As a result, medical data mining adds to business intelligence, which is beneficial in illness diagnosis. This paper discusses data mining methods for medical data, specifically for illnesses that are discovered and diagnosed for human health. Despite the fact that this study presents numerous possibilities and methods for big data analytics in healthcare, there are many more avenues to be investigated in the future, including different elements of healthcare data, such as quality, privacy, timeliness, and so on. This section gives a general overview of big data analytics in healthcare informatics, including themes like healthcare data characteristics (e.g., high complexity, huge size), data analytics activities (e.g., longitudinal analysis, visualization, etc.), and goals (e.g. real-time, privacy protection, collaboration with experts, etc.). The rapidly growing digital health data will help the future of health informatics.

Data mining applications may be very beneficial to the healthcare sector due to their applicability. However, it should be noted that the value of this advantage is contingent on the quality of the data. To guarantee the effectiveness of data mining applications, the collection, storage, preparation, and mining of data must all be carefully addressed, with a common clinical language and data-sharing strategy across healthcare organizations. Furthermore, beyond quantitative data, the breadth and type of healthcare data may be extended. Text mining may be used to extract information from physicians' handwritten medical notes and records. The method may be improved by combining data and text mining. Furthermore, data mining has progressed thanks to the use of digital diagnostic pictures. The researchers are optimistic that the results of this study will help improve data mining and healthcare resources, benefiting all parties involved.

ANALYSING EXPRESSION DATA USING FUZZY LOGIC ALGORITHM

Dr. Kashif Qureshi*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: kqureshi.cse@sanskriti.edu.in

ABSTRACT

Logic for gene expression analysis in a flurry. We developed a novel technique for analyzing gene expression data. To convert expression values into Quality descriptors, this approach uses a fluid logic that may be evaluated using heuristic criteria. We developed a model for identifying three distinct activators, repressors, and goals in a data set for yeast gene expression in our studies. The test predictions produced by an algorithm match the experimental data in the literature quite well. Algorithms can discover a far larger number of transcription factors that could be found at random in determining the function of undefined proteins. Using just expression data in the form of clustering, this technique allows the user to construct a connected network of genes. The interpretation of gene expression categorization models is usually difficult, yet it is an important part of the analytical process. We investigate the performance of small rules based on fuzzy logic in five datasets that vary in size, laboratory origin, and biological domain. The classifiers resulted in rules that are simple to understand for biomedical researchers. The classifiers resulted in rules that are simple to understand for biomedical researchers.

KEYWORDS:*Algorithm, Expression, Fuzzy Logic, Gene, Models.*

1. INTRODUCTION

Complex data mining techniques such as vector support machines, neural networks, and logistical regression were used to categorize gene expression data. They create models that are difficult for biologists and biomedical researchers to understand because to the large number of variables and factors. It would be much simpler to understand models if simple but exact rules could be generated from a little amount of training data.

People are better capable of understanding simple rules, such as 'when A is up regulated and B is down regulated,' than equations containing many coefficients, interaction conditions, and constants; some writers suggested adopting rules-based systems to analyze microscopic data.[1].Computational time stymies the creation of increasingly complex fuzzy models. Pre-processing data may be a viable option. If three genes are determined to be unlikely to fit the model before the algorithm is run, the implausible triplets may be ignored if the technique is run,

decreasing the number of triplets not examined in subsequent stages to a reasonable amount of time.

To discretize the data, many methods depend on a limited number of categories. Discretization is also advantageous since it makes data interpretation easier. The results obtained by microarrays are very accurate. Who should, however, be addressed in the communication? The meaning of this apparent precision is debatable. The values are read by scanners that measure the degree of fluorescence in the various colored channels. Because the process is vulnerable to saturation and other mistakes, biologists usually rely on experiments rather than absolute gene expression data to estimate the amount of mRNA[2]. Given human perception, reducing the numerical scale to an ordinal, in broad categories such as epiregulin, neutral, or downregulation, is possible (and desirable). Furthermore, rather of using real numbers multiplied by specific coefficients to produce a classification device, this reduction may be utilized to create simple principles that people can understand (as is the case in other modelling approaches). Two kinds of algorithms are needed to infer these rules from the data: algorithms for categorizing continuous values and algorithms for rule discovery and filtering that result in compact, understandable rules. Crisp's discretization ignores the possibility that border values across value categories are very comparable (in opposition to fussy discretization) [3]. By integrating membership values from several categories, it is possible to select a sample at the high end of the "low" category, for example. Please keep in mind that fluid memberships are unlikely, and their operators are not the same as those used in that context.

Rather than numerical numbers, fuzzy set-based computations are referred to as 'computations.' The methods contained in this paper combine fuzzy discretization of operators with induction as well as filtering algorithms developed specifically to generate a small series of short regulations useful for modeling (assignment of membership values to discrete values such as low, medium, and high or benign, malignant) and flouted operators. In several respects, this research broadens the area of flushing discernment, automates rule induction and filtering, and compares a larger number of datasets[4].

1.1 Fuzzy logic Algorithm:

The definition of fuzzy logic is a many-valued logic form in which the truth values of variables may be any real integer between 0 and 1. After evaluating all relevant facts, the fuzzy logic method aids in the solution of a problem. Then it makes the best choice feasible based on the input.Fuzzy logic is utilized in Natural Language Processing and a variety of Artificial Intelligence applications. Modern control systems, such as expert systems, make significant use of fuzzy logic. Fuzzy Logic is utilized with Neural Networks because it simulates how a human would make choices, but much more quickly.

1.2 Clustering to Improve Run Time:

The categorization of genes according to their expression is the first step toward a comprehensive and fast data analysis. It is usual to use clustering to group genes with similar expression patterns. Gene clusters may be used to give metadata for gene datasets. If a particular mix of clusters does not match the model well, it is unlikely that other genes with similar expression profile would fit the model well.

Because we believe the data can be clustered such that the majority of gene expression profiles are relatively near to cluster centers, the cluster centers and their associated gene profiles are similar, and the MSE difference is small[5]. As a result, if the model doesn't match well with a set of cluster centers, the genes around these cluster centers won't fit well into the model either. With prior knowledge of how cluster centers fit into the model, we may exclude combinations of

genes whose closest cluster centers do not fit into the model. As a result, we can save a lot of time by not looking at these combinations in the hazy model.

Although clustering does not allow us to find direct links between genes, it does allow us to effectively reduce the dataset to a few time series that accurately represent the data in general. We may claim that the expression profile of the cluster centre is substantially similar to the cluster genes if the standard difference between genes and their associated cluster centre is small[6].

1.3 Improved Algorithm:

The methods for evaluating gene expression data in the modified Woolf and Wang approach are discussed in this section. The technique is first implemented using triplet cluster centers with no error or variance constraints. Each triplet of cluster centers is categorized according to their inaccuracy in the model. The method is then applied to the genes. Before gene analysis, a file containing all triplets of the cluster and their faults in relation to the model is read. The cluster's triplets are separated by the target. There are two methods for assessing the centers of the clusters to which they belong:

- **Percentage Ranking Method:** The matching cluster triplet for the target gene cluster must be above a certain percentile. The ranking for cluster triplets is determined by the model error, with a lower error indicating a higher rank.
- **Error-Threshold Method:** In each cluster combination, a mistake score must be less than a previously specified threshold. If the related triplet cluster of the triplet gene fails to reach the specified threshold, triplet.is skipped and the algorithm moves on to the next triplet.

1.4 Developing a Generalized Model:

The generalised model is based on the idea that reactants should be kept to a minimum. To make a complex, all of the proteins in it must be present. If one or more of the genes are underexpressed, the proteins encoded by those genes will be underexpressed, resulting in inadequate complex expression due to the absence of critical component proteins. Complexes are unlikely to have a significant effect on target gene expression if not all activators or repressors required for activation or repressions of the complex target gene are substantially expressed.

Let X be a gene expression matrix containing gene expression profiles (in the basic model, X consists of two vectors xa and xr representing two expression profiles, i.e. activator and repressor, respectively), and let y be a model output, defined as y=f (X). The optimum expression profile of the target gene is represented by the y output. Let z be a vector that represents the target gene expression profile in real time. xa, xr may be extended to Xa and Xr, which are matrices with an arbitrary number of activator or repressor profile vectors.

Assume, there exist vectors x_{ma} and x_{mr},

Wherex_{mai} = min (x_{a2i}, x_{a2i} …xaji)

x_{mri}= min(x_{r2i}, x_{r2i}, … … …x_{rji})

where j is the activator number in Xij k is the repressors number in Xij and i=I, 2.

A' where N is the expression profile number. Now, xij and x contain the minimal level of expression for each of Xi and Xj's genes, at every point of expression. We may suppose that, because of the limiting reactants, xij and x are an expression profile of the activator/pressure complex. Therefore, we may utilisexij and xi as models. If we assume that we have the same assumption as Woolf and Wang did with the basic model if the mean quadratic error between the model output y and the expression profile of the target gene z is minimal.

1.5 Fuzzy rules:

If U is a collection of samples of tissues, let G = $\{g_j\}_j$ be a set of symbols of a gene, let C be a set of class labels and allow c: U as C be a partial function which applies classes to U as a result of U as a whole. Let g(x) indicate the value of the tissue sample gene g expression x. According to the aforementioned assumptions, genes are controlled at a qualitative level such as up (u), neutral (n) or downwards (d). Let L be the collection of such standards. We combine a fluid set and allow μ(l, G, x) to form part of X with the gene g and level l for each gene or qualitative level[7].

May the above-ground descriptors be D = G = L. In a proposal context, the descriptor d=(g, l) is often seen in U {x alternate with U|g(x) = l{}. This allows d to be used for a set of elements in U for which g(x) = l may be seen as a function. This view is expanded to a member function, allowing g(x) in l to include the descriptor d. In other words, with the descriptor d = (g, l) we have this d(x) = μ (l, g, x). This allows the typical crook-free combination and disconnection, as less (and max) of 2 feature functions, to be extended straight to the standard flush case.

The R = 2D = C rule is defined as an element. We designate the antecedent D by ant(r) for a rule r = (D, c), and thus c of r by cons (r).

The application r(x) of a rule r = (D, c) in respect of the element x = U shall be defined as r(x) = min d in respect of the element D(d(x) in question. (1) We consider that r(x) is the x membership of class c in accordance with r. Our idea of membership is extended to a collection of R rules and is classified accordingly. The c-type of a c-type is μR(c, x) = max({0}).

By selecting one with a maximum membership, we may now assign a class to x. In some cases, if you cannot be sufficiently sure that a case is a class, it is occasionally helpful to be able to disregard a categorization. This is how we implement this concept. If x > 00 else, leave s(x) = x.

Also add a threshold tc to every class label c = C. The tc threshold is the threshold for which class c is rejected. What we mean by categorization may now be defined properly. Given the corresponding tc criteria, the categorization of x to be determined by R is defined. Functions for length three sequence classes with R maximum membership. Formally, classR(x) = arg max c∈C (s(μR(c, x) − tc)).

If classR(x) contains more than one element, we decide to reject the classification. This happens if all classes have either been rejected or many classes have the same maximum membership for x.

1.6 Learning Membership Functions and Rejection Thresholds

In order to apply a set of rules, we must know in the rules the membership functions that are consistent with the descriptors and the refusal levels for each class label.

We present a simple system, which allows us to learn both the membership features and the refuse thresholds given a set U = U.

The triangular functions result in a sequence of length three. Our set of labels L are now ordered to have a quality of the meaning of the li mark lower than the lj mark for 0 <i<j to n − 1. An instance is that of L = {l0, l1}, in which l0 = "down" and l1 = "up." Increased sequence of real numbers sg n = |L| is associated to each gene g. We are now allowing μ(li,g,x) = μi(x), where μi for sequence sg is described above. We propose to utilise quantiles in the gene g sequence U over observed expression values, assuming expert knowledge dictates nothing else.

We used n = 2, v0 = min(g(U)) and v1 = max(g(U)) in our experiments.

Having determined the membership functions, we propose the rejection threshold for class c.

Then the tc threshold is the minimum non-zero assignment across U. We suppose that it is useful to carefully pick the training set U, preferably in cases where partial function c is specified.

2. LITERATURE REVIEW

P. Woolf et al. discussed about a fuzzy logic approach to analyze gene expression data[8].A novel algorithm for analyzing gene expression data has been developed by the author. This method use fuzzy logic to convert expression values into qualitative descriptors that may then be assessed using a set of heuristic criteria. We used a model to find triplets of activators, repressors, and targets in a data set of yeast gene expression. The algorithm's predictions for the circumstances studied match well with experimental evidence in the literature. The algorithm can also help with determining the function of unknown proteins and can detect a much larger number of transcription factors than could be discovered by chance. This method improves on existing techniques like clustering by allowing users to create a linked network of genes based only on expression data.

HabtomRessom et al. discussed about theefficiency of fuzzy logic-based gene expression data analysis[9].DNA microarray technology allows for a comprehensive study of gene expression in an organism. Researchers may be able to reverse engineer a genetic network using the amount of spatiotemporal data produced by this technique. A technique called "fuzzy logic" has been suggested for analyzing gene connections and aiding in the deciphering of a genetic network. By evaluating all combinations of gene expression patterns, this approach may find interacting genes that match a known "fuzzy" model of gene interaction. In terms of computing speed and noise resilience, this article presents advances achieved over prior fuzzy gene regulation models. The use of cluster analysis as a preprocessing technique to decrease the total number of gene combinations examined improves computing speed. This method improves the algorithm's speed by a factor of 50 while having little impact on the outcomes. The sensitivity of the model to noise is minimized by using suitable techniques of "fuzzy rule aggregation" and "conjunction," which provide trustworthy results even when the model input varies little.

Lien-Chin Chen et al. discussed aa weighted fuzzy-based biclustering method for gene expression data[10].Biclustering is a popular gene expression data analysis technique for identifying a group of genes with similar expression patterns. Despite the fact that several biclustering algorithms have been developed, few have offered a query-driven method for biologists to search for biclusters containing a specific gene of interest. In this work, we present a generalized fuzzy-based method for extracting a query-driven bicluster based on a user-defined reference gene, called Weighted Fuzzy-based Maximum Similarity Biclustering (WF-MSB). Significant biclusters in expression levels are extracted using a fuzzy-based similarity measurement and condition weighting method. WF-MSB finds both the most similar bicluster and the most different bicluster to the reference gene. On actual yeast microarray data and synthetic data sets, the suggested WF-MSB technique was compared against MSBE. WF-MSB can successfully identify biclusters with important GO-based functional meanings, according to the experimental findings.

3. DISCUSSION

Overall, the algorithm's findings match the experimental data in the literature. This isn't surprising since the program looks for links that match our understanding of how an activator, a repressor, and a target interact. As a result, the fuzzy logic algorithm simulates the mental process that an expert would use to analyze this data, using basically the same criteria that an investigator would use to identify a protein's regulatory role. However, the algorithm is automated, unbiased and wide in contrast to an expert. Expression data may be difficult to assess, and if not thoroughly examined, it can easily be misconstrued. We developed a "lens"

through which the results may be sorted without difficulty, quickly and efficiently, utilizing a data processing calculation technique.

Although the algorithm was used in this study to find the activator, repressor, and target genes just three times, additional technique variations are also possible. The activator repressor model is a simple method to demonstrate that this technology may produce physiologically realistic results. However, the technique is general and may be used to more complicated interactions and systems.Rather than providing quantitative predictions, the goal of this approach is to draw broad patterns that relate to a large number of genes. As a result, including some nonlinear effects would not help create many connections, but would add a significant computational burden to an already difficult job.

This technique is mostly used to independently verify or discover pharmaceutical targets. Traditional therapeutic target identification methods require a thorough knowledge of the disease's biology, which may be time-consuming and difficult to accomplish. Expression profiling, on the other hand, is a quick, high-performance technique that delivers a large amount of cell information in a format that can be easily processed by a computer. A fuzzy logic method for analyzing expression profile data may be used to validate the mechanism of a given goal. Furthermore, since the fumbling logic approach does not need any biological gene expertise, genes with unknown functions may be inserted just as easily as genes with known functions. This ability to identify functional indications of uncharacterized génes is a significant advantage in the creation of medicine targets, since potential drug targets may be linked back to the detailed biology.

4. CONCLUSION

Author demonstrate how clustering may save time as a pre-processing step in the construction of a fluid, logic-based model in this paper. In contrast to a modelling approach used in previous years that analyzes all gene combinations, our method utilizes self-organized mapping cluster centres to identify genes that may interact. This approach facilitates the creation of complex models, such as co-activators and corepressors, by speeding up the process of modeling gene interaction. This will increase the attractiveness of fuzzy algorithms for reversing the gene expression network.

There is presently no precise method for determining the number of clusters to keep and the percentage of cluster combinations to keep. We found that the number of clusters in a dataset from one of the four public databases used should be at least half the number of time points. When the number of clusters is increased beyond that, many clusters with similar features emerge, providing minimal information to the clusters. We're looking at using a double self-organizing map (DSOM) and adaptive resonance theory to find the right amount of clusters (ART). When it comes to selecting the proportion of cluster combinations to be preserved, 67 percent seems to be appropriate; there are significant improvements between 50 and 67 percent, but little, if any, improvement between 67 and 75 percent.

The methods presented in this paper may pave the way for the creation of a generic gene regulatory model that can be applied to any number of genes. The improvements will make utilizing fuzzy logic to analyze gene relationships using current micro array techniques more feasible.

DISCUSSION OF ANTIMICROBIAL RESISTANCE IN THE ENVIRONMENT AND ITS IMPLICATIONS FOR ENVIRONMENTAL REGULATORS

Ms Namrata Arya*

*SBAS, Sanskriti University, Mathura,

Email id: namrata.sobas@sanskriti.edu.in

ABSTRACT

The significance of the environment in the worldwide development of clinically relevant antimicrobial resistance is being more acknowledged. Most of those routes responsible for both the release of resistance-driving substances into the environment are monitored and controlled by environmental authorities (e.g., antimicrobials, metals, and biocides). As a result, environmental regulators would play an important role in the creation of global and national antimicrobial resistance action plans. The lack of environmental mitigation actions in current AMR action plans is argued to be a result of our lack of fundamental understanding of many of the key issues. Therefore, we'll look at the issue of AMR in the environment through the eyes of an environmental regulator, using the Environment Agency as an example to draw worldwide parallels. Provide many thought experiments to demonstrate how various mitigation methods could work. Conclusion: AMR Action Plans do not cover all potentially relevant AMR routes and causes in the environment; and AMR Action Plans are inadequate in part due to a lack of research to guide policy, which needs to be tackled.

KEYWORDS:*Antimicrobial Resistance, Amr, Antibiotics, Biocide, Genes, Metals, Plasmid.*

1. INTRODUCTION

Many of the obstacles to fighting antibiotic-resistant infections in the clinic are well recognized, and as a result, they have been included into current antimicrobial resistance Action Plans. It is claimed that the absence of any major environmental emphasis in current AMR Action Plans and the O'Neill AMR Reviews is due to our failure to properly address basic concerns regarding AMR in the environment. It is also claimed that AMR Action Plans are inadequate and risk failing to achieve the intended objectives of guaranteeing and enhancing the effectiveness of current and future antibiotics if all causes and routes of AMR into the environment are not included or considered[1].

We want to illustrate the AMR problem through the eyes of an environmental regulator in this study, utilizing the Environment Agency as an example from which worldwide parallels may be made. We suggest that there is an evidentiary gap that limits policymakers' and environmental

regulators' capacity to safeguard the environment from AMR[2]. The method used by an environmental regulator in dealing with the AMR issue is shown by the following five questions. The inability to answer these questions at this time shows some of the evidence gaps that must be addressed in order to enable the development of a comprehensive, evidence-based AMR Action Plan:

Finally, we present several hypothetical scenarios for how various mitigation strategies might work in light of a comprehensive understanding of AMR drivers and pathways. This study is intended to serve as a springboard for future conversations between scientists, politicians, physicians, veterinarians, and regulators[3]. We also hope that this review will prompt a more comprehensive evaluation and meta-analysis of the literature in order to further evaluate and criticize the evidence base and the changing status of our knowledge gaps.

1.1.Overview On Amr Action Items At The Global, Regional, And National Levels

The World Health Organization (WHO) has outlined five strategic goals to combat AMR in its Global Action Plan:

- To raise AMR awareness and comprehension;
- To improve knowledge by conducting surveillance and study;
- To lower the risk of infection;
- To make antimicrobial agents more effective; and
- To ensure long-term investment in antimicrobial resistance.

“Establish standards and guidelines the presence of antibacterial agents and their residues in the environment, – particularly in water, wastewater, and food,” says the WHO in Goal 4 of both the Action Plan. The European Commission released a similar action plan. The O'Neill AMR Review, which is discussed below, also emphasizes pharmaceutical manufacturing. Although rivers receiving wastewater from medication factories have been demonstrated to be a major local problem with global consequences, it will be used in the next sections that it is just one of many possible pathways. Furthermore, it will be demonstrated that antibiotics are only one of many environmental drivers of AMR[4].

In a similar vein to the WHO and EC AMR Strategic Plan, the last Review on Antimicrobial Resistance, titled “Tackling drug-resistant diseases globally: Final report and recommendations,” emphasized the need to minimize antibiotic pollution in the environment. In a nutshell, it identifies three paths:

- Animal waste
- Human waste
- Waste from the manufacturing process.

Antibiotics were the focus in every instance, with no mention of other resistance-inducing substances. Two routes are also prioritized: hospital wastewater and pharmaceutical production facilities. It's tough to argue against enhancing these two routes, since they're both very important at a geographically resolved scale of analysis; nonetheless, their inputs are little in comparison to the massive input of all resistance-driving chemicals from all sources (see Figure 1). Furthermore, it is unknown if WWTPs that receive hospital wastewater release substantially more resistance-driving chemicals into the environment, with demonstrably higher effect, than other WWTPs of comparable size[5]. Hospitals are an easy target and, in many respects, a tractable target, but that does not mean they should be the first priority for decreasing AMR prevalence in the environment. The vision for these action plans, it is claimed, is not sufficiently

comprehensive to protect our natural environment. To understand these criticisms, one must first comprehend what causes AMR in the ecosystem.

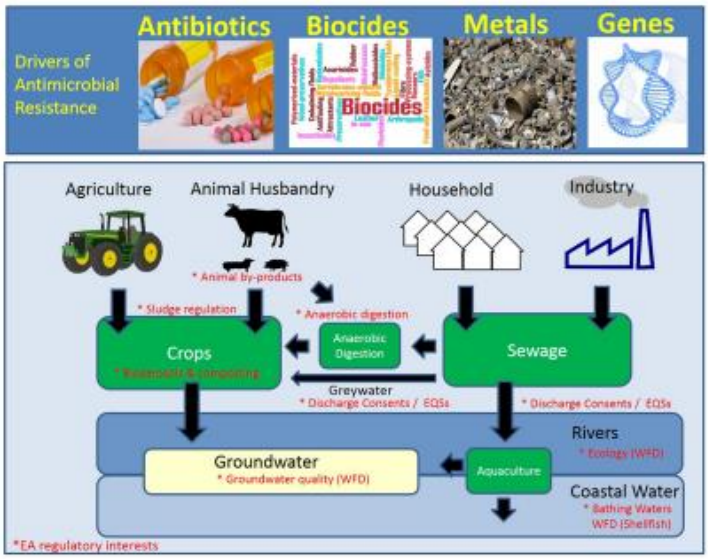

Figure 1: | Schematic of the hot-spots and drivers of antimicrobial resistance (AMR)

1.2.Antibiotics Are Among Main Causes Of Resistance.

1.2.1. Antibiotic Use In Humans On A Large Scale

In 2013, the equivalent to the quantity consumption of antibiotics in England was 27.4 DDD per 1000 inhabitants each day, which was in line with the European median of 21.3 DDD per 1000 inhabitants per day in 2011. The DDD is the assumed average maintenance dose each day for a drug being used for foremost indication in adults, and the DDD is the presumed average maintenance dosages each day for a drug being used for primary indication in seniors. Medicines were given for a total of 66 different infections, with the top 15 antimicrobial in general practice and hospitals representing for 98 and 88 percent of use, respectively. When it came to overall tonnage, India was the biggest user of antibiotic in 2010, but their per capita consumption was low when compared to Australia and New Zealand, which had the highest consumption rates of 87 and 70 units per capita, respectively. In this research, an antibiotic unit were expressed as the ratio of doses sold. China, like India, was the world's second-largest user of antibiotics in terms of overall tonnage, but had comparatively low antibiotic consumption per capita[6]. Heterogeneity in antibiotic usage seems to be replicated on a global basis. For example, disparities between nations within smaller areas, such as Europe, where Turkey used almost 300 percent more antibiotics per capita than Armenia, are nested inside broader worldwide differences. French and Greece have the largest specified daily dosage of antibiotics per capita in Europe, with both the United Kingdom surpassing the lowest usage European nation, The Netherlands, by 33%. Differences across nations are often linked to the ease for which one may self-medicate, with central and eastern European countries having more accessibility to antibiotics without the need of a prescription, resulting in increased usage and abuse. Antibiotic usage per capita in Europe is least in northern areas, moderate in eastern areas, and greatest in southern areas.

1.2.2. Antibiotic Use In Animals On A Large Scale

According to The State of the World's Antibiotics 2015, animal husbandry uses two-thirds of all antibiotics manufactured worldwide each year. Even within high-income nations, there may be substantial differences in veterinarian antimicrobial usage in food-producing animals. Norway

has the lowest sales of veterinary antimicrobial drugs among the 26 EU nations in 2013, measured in mg of antibiotic per population correction unit. PCU is a standard unit of measurement that considers the animal in a nation and their total amount at the point when they are most likely to be treated, resulting in an assessment of total kg of food-producing animals in the country. Italy, Spain, and Cyprus were at the top of the EU in terms of veterinary antimicrobial usage. The tetracycline and penicillin antibiotic classes account for the bulk of these sales, accounting for 6–56 and 11–61 percent of total antibiotics marketed in each nation for food-producing livestock, respectively[7]. These three types of antibiotics, in conjunction with sulfonamides, accounted for 71% of total sales within those 26 European Union/European Economic Market nations in 2013.

1.2.3. Greywater, Reclaimed Water, And Black Water Are All Types Of Water.

Greywater is described as water from the mains public water supply that's been used for bathing, washing dishes, or laundry, but not for toilet water. Reclaimed water is usually WWTP effluent that has been treated further to ensure that it is suitable for use in a number of purposes, such as irrigation and toilet flushing. Blackwater is sewage wastewater that has been recycled and processed. The Environment Agency would need Discharge Consent for the use of reclaimed water for irrigation, and it would have to meet British Standards. While sewage wastewater must satisfy treatment standards established by different states before being used for irrigation in the United States, animal feeding lot wastewater does not have to be treated before being applied to the soil.

Manure and sludge are applied to the land. Sludge or ‘bio solids,' a WWTP waste material rich in organic protein, oils and fats, as well as microbes and undegraded medicines, the latter of which may represent hundreds of distinct compounds ranging from sub-ng/L to >10 g/L, is produced by biological wastewater treatment. The Sludge Regulations and the Code of Practice for the Agricultural Use of Sewage Sludge govern all bio solids used on agricultural land in the United Kingdom. The rules are mainly concerned with the effect of metals in the sludge on the receiving soil and nearby water bodies, but they also cover any component of both the sludge that reduces agricultural production or puts adult or child health in danger, either directly or indirectly via the food chain.

1.2.4. Ecological Relevance Of Antibiotic Concentrations

In clinical contexts, the well-established lowest concentration pertains to the doses required to inhibit or kill a specific pathogen. The amount at which a bacterial strain provides a selection advantage to its ‘host' must be less than the MIC, or the microorganism will die. The MSC is a useful word that refers to the minimum concentration of chemical needed to give a selection edge to microorganisms having the resistance gene compared to a bacterium that is susceptible to the chemical, i.e., does not have the resistance gene. Whenever applied to even more realistic situations of many species and various chemicals, the MSC is a theoretical threshold that can be precisely established in the laboratory for every microbe and chemical combination, but it takes on a new meaning. MSCs for more complex processes are still being determined, and their more realistic circumstances may provide additional insight into the ecological significance of low antibiotic concentrations in the environment[8]. A variety of biological and physical properties variables have been found to affect the MSC. Homogeneity in antibiotic concentrations due to uneven partitioning into soil pores, sediment, biofilms, and organic matter is believed to play a key role in enabling antibiotic resistant and sensitive bacteria to coexist. The screening and survival of the more prevalent, frequent small-effect mutations is enabled by heterogeneity in the exposure of bacteria to weakly selective sub-lethal antibiotic doses within a matrix.

1.2.5. Biocides Are One Of The Main Causes Of Resistance

Biocides are disinfectants widely used in hospitals, cosmetics, home cleaning products, wipes, and furniture preservative, along with farmyards for wheel and foot washes and a variety of industrial operations, such as the prevention of fouling and souring of pipelines, including oil wells. Ethanol, formaldehyde, chlorhexidine, triclosan, and quaternion ammonium compounds are examples of common biocides. The Biocidal Substances Regulation governs biocide marketing, usage, and disposal in Europe[9].

1.2.6. Biocides' Relevant Mechanisms

Biocides affect the atmosphere in the same way as antibiotics do, via WWTPs. Improper biocide disposal, such as dilution and discharge to WWTPs, may increase the load of biocides released to the environment, as well as the possibility of resistance developing.

1.2.7. Metals Are Resistance Drivers

Household wastewater, drainage water, commercial effluent, atmospheric deposition, and traffic-related pollutants are all major sources of heavy metals in metropolitan areas. Food, clothing, home, industrial, and medical goods, as well as disinfectants, now include metal nanoparticles. Pb, Cu, Zn, Cd, and other metals have been employed in aquaculture and agribusiness as animal growth boosters and nutritional supplements, fertilizers, insecticides, and fungicides.

1.2.8. Metals' Relevant Connections

Metals follow similar routes to biocides and antimicrobials; but, depending on the presence of industry, agriculture, or waste water/storm water, the proportional percentage of each source is likely to vary. Rivers downstream of metropolitan centers, where storm water runoff is severe, and places where mining has occurred, are often affected by increased metal. The ecological significance of these diffuse and point sources of metals to the selection for resistance in the environment is yet unknown.

1.2.9. Antibiotic Resistance Genes Are One Of The Main Causes Of Resistance

Antibiotics are released into WWTPs on a regular basis, which coincides with the emergence of resistance genes. Resistance genes in wastewater come mainly from people' gastrointestinal tracts. Antibiotics and ARGs co-located in WWTPs can select for novel AMR combinations that can be shared between microorganisms via horizontal gene transfer on mobile genetic elements (MGEs), such as plasmids, resulting in an increase in the prevalence and combination of multiple drug resistance in the microbial community. The competitive and chemically demanding environment of a sewage treatment plant provides ideal circumstances for the amplification of existing resistance genes, the development of new resistance genes, and the formation of genomic assemblages[2]. Antibiotics may cause the bacterial SOS reaction, in which bacteria experience a brief genome-wide hyper mutation, resulting in genetic diversity under stressful situations. The SOS response may also induce ARG HGT, providing a route for ARG dissemination after antibiotic exposure. Abiotic sources have been discovered as one of several additional HGT factors. At an ecologically relevant scale, the relative significance of each of these HGT drivers has yet to be determined.

1.2.10. Separation From A WWTP

Antibiotics, biocides, metals, and ARGs are all introduced into STPs, but they are released as part of the: (1) effluent, and (2) sludge. Sludge may be composted, anaerobically digested, and then put to soil, or it can be burned. The percentage of antibiotics, metals, and biocide in effluent and sludge varies significantly depending on STP catchment features, the presence of hospital wastewater, the type of the STP, and its operating parameters[10]. ARGs that are liberated in treated wastewater are not completely removed by WWTPs. Sewage effluent is diluted when it enters a river, estuary, or coastal body of water. Pollutant concentrations will interact with local

flora and fauna, changing the structure and genetic composition of the microbial community. Changes in the microbial population caused by a variety of causes, including pollution, have been demonstrated to have a substantial effect on the diversity and functioning of ecological processes above ground.

DISCUSSION

The atmospheric regulator's significance of AMR routes and drivers may be stated in three major highlights: Low quantities of antibiotics, metals, and biocides in sewage effluent, rivers, sludge, irrigation systems, aerosols, aquaculture, industries, and groundwater may directly select for ARGs within the AMR pathways that are within the jurisdiction of the Environment Agency. The Environment Agency is responsible for the spread of antibiotics, metals, biocides, and ARGs into animals, plants, food, groundwater, rivers, and bathing waters. Antibiotics, metals, and biocides have sub lethal impacts on organisms, associated microbiome, and ecosystem services (e.g., rivers, coastal waters, and soil), which may have an influence on the health, production, and safety of economically significant food items as well as the broader biome.

CONCLUSION

It is critical to recognize that now the development of environmental emphasis in AMR Action Plans and indeed the O'Neill Review is, arguably, due to the following reasons: our understanding of AMR inside this environment is so lacking that there is very little that can be suggested for mitigating the impact without using the precautionary principle as the primary rationale for action, and the disciplines of pollution, environmental microbiology, and public health are all lacking in environmental focus. Unless society is willing to bear the non-trivial expenses of a conservative approach, such as higher water rates to pay for significant improvements in WWTPs, there will be a need to prioritize research that solves the previously mentioned "Knowledge Gaps." The fact that such an investment in improving WWTPs may result in numerous "victories" via the elimination or decrease of other pollutants and dangers should not be overlooked. There is reason to be hopeful, however, since for the first generation, the seven UK Research Councils have joined forces to finance long-term cross-disciplinary, integrated research on AMR. A Funders' Forum against Antimicrobial Resistance has also been formed to offer a framework for providing a better integrated research portfolio and maximizing the effect on both national and international policies and actions.

ABSTRACT

This article examines recent advancements in the area of sensitive texture sensors and electronic material advances, which is rapidly changing and evolving. It summarizes the basic standards and methods used in the construction of texture sensors, as well as the most often used materials and processes in electronic materials. This study demonstrates that depending on the degree of mixture into the texture stage, inborn and external changes to material substrates may be used to determine utility. Texture sensors may be custom-made to measure power, pressure, synthetic chemicals, moistness, and temperature variations, as shown in this study. Materials, connections, texture circuits, interconnects, epitome, and creative methods linked to texture advancements are versatile and flexible, but less powerful than its traditional hardware counterparts. The findings of this review suggest that by combining several types of material-based utilitarian components, a complete keen texture framework is possible. This study serves as a first step in standardizing brilliant texture detection algorithms and e-material production methods.

KEYWORDS:*E-Textiles, Fabric Sensors, Textile Sensors, Techniques.*

1. INTRODUCTION

Textures are the newest silicon wafers, and their emergence of useful devices and exquisite figure has piqued attention. Despite the fact that this was not a replacement for conventional devices, this sector has a market that is now in its early stages of development since it lacks a standardized set of systems or components. It has evolved into a byproduct of wearable technology advancements. This article includes a review of important developments for improving textures with long-term utility, with a focus on electrochemical sensors[1]. Sharp texture sensors (SFSs) are textures that are penetrated with detecting characteristics; they are sensitive to a variety of physical and chemical changes, such as changes in temperature, pressing factor, power, and electrical current, among others. At any level, detecting components may be merged into textures if the underlying texture component is changed or sharpened. SFSs are required for the more generalized class of smart texture transducers (SFTs), which are textures that have been manipulated or changed to serve as sensors, actuators, or perhaps other types of

transducers. The omnipresence of textures makes them an excellent vehicle for the deployment of sensors in close proximity to humans[2].

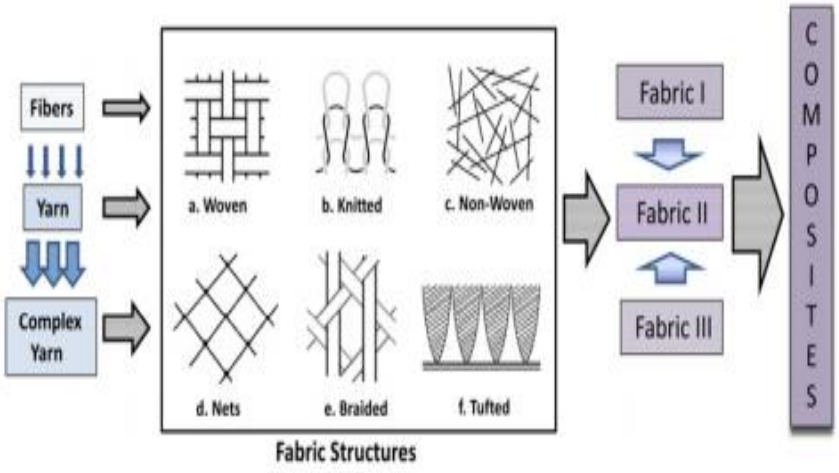

Figure 1. Fabric construction platform and hierarchy. Fabric structures: (a) woven, (b) knitted, (c) non-woven, (d) nets, (e) braided and (f) tufted, which can be assembled in layers (e.g., three layers) to form composite structures

SFSs are influenced by the fabric structure platform. Curtains are fibrous materials with a hierarchical structure. Muscle fibres are the smaller units, or initial level of integration, which are distinguished by a high length-to-thickness ratio; these components interlace to create thread. The second stage of integration occurs when thread is twisted to create yarn. Yarn is transformed into fabric, the third stage of integration, via a variety of methods also including weaving and knitting. Synthesis or compound fabric units are used at larger sizes of hierarchical levels[3]. The basic development of fabric structures, from fiber to cloth, is shown in Figure 1. A distinction must be noted: thread is often referred to as yarn; however, yarn is typically thicker than thread, and it may be produced directly from the component fibers in certain cases. Textiles were defined as any substance that is made up of fibers. Fabrics are included in this category, as is any material created by weaving, knitting, or other fabrication methods. A fabric utilized for a particular purpose is referred to as cloth. Textiles and fabrics are being used interchangeably in this study.

The type or origin of the fiber units, which may be natural or synthetic and regenerated, is an independent element that influences the fabric's ultimate properties. Synthetic fibers offer a higher mechanical compliance and far less water absorption compared natural fibers. This nature of the fiber affects a fabric's sensitivity to chemical and photonic reactions, coating compatibility, adhesion, water absorption, overall fabric lifespan, thus the origin of fibers used in STF design should be a key design concern[4]. The humidity absorption characteristics of some fibers, for example, may impact their dimensional stability, along with inherent mechanical, frictional, and electrical properties, as well as their form, stiffness, and permeability. If metalized connecting components are to be integrated with the fabric structure, a hydrophobic platform may be chosen to minimize the risk of short circuits caused by perspiration or excessive humidity. Hydrophilic textiles, on the other hand, may reduce the accumulation of static electricity, which may be a danger to electronics boards connected to the bottom of an SFT.

- *Sensors.* Fabrics which are given sensing properties of diverse physical nature, such as capacitive, resistive, optical and solar[5].

- *Actuators.* Fabrics which are able to actuate or move some aspect of their environment. Examples of these types of fabrics are electroactive fabrics and axenic fabrics.
- *Batteries and energy harvesting.* Fabric based batteries sand fabrics which use the kinetic energy or the thermal energy of the wearer or their environment to generate electrical power.

1.1.Improvements To The Platform For Smart Sensing Capability

Fabric platforms or substrates may be changed at any level of the structural hierarchy to convert them into SFTs. All of the platform changes that will be addressed directly apply to SFSs for the purposes of this study. The creation of fibers composed of conductive materials through which a textile may be produced would be a level-one alteration. The exchange of yarns with sensitive yarns would be a level-two modification. This is what e-textiles look like. A level-three alteration would include changing a fabric's surface, such as with a coating, to give it perceiving capabilities[6]. The employment of several sensing fabrics to create a sensing composite would be a level-four modification. All of the sensors described in the next sections may be categorized as having undergone intrinsic or extrinsic changes, a distinction that will be addressed later.

1.2.Extrinsic Changes To Enable Sensing Capabilities

Improvements to the fabric structure that allow sensing features may be made at any level. Fabrics that have been changed extrinsically, i.e. by adding discrete or self-contained sensing components, are known as "electronic textiles," and they typically include the superficial attachment of ordinary electronic parts such as resistors or integrated circuit chips to the fabric. Extrinsic or exterior modifications to fabric substrates, such as fiber, yarn, or woven fabric, include coatings. Screen printing, ink-jet printing, electrodeposition, ultrasonic cleaning plating, sputtering of thin films, vapor deposition, and thermoset coatings are some of the coating methods used in fabric sensors. The tensile, shear, and bending characteristics of textiles are all affected by coatings[7].

1.3.Intrinsic Fiber, Yarn, And Fabric Sensor Characteristics Changes And Design

Materials that are responsive to mechanical or chemical stimuli may be used to make fibers and yarns. As fibers and yarns are replaced by sensitive fibers and yarns, integration may become more interwoven, to the point where sensing components are created from fabric materials themselves. Passive and active electrical circuit components have been claimed to be constructed from conductive yarn and other soft materials. Embroidery and silk screening of conductive fabrics are two of these techniques. Fibers composed of sensing materials may be produced in a variety of ways, both standard and unusual. Some of the techniques used to create fibers out of sensing materials include electrospinning, wet-spinning, self-assembly, carding, combing, and die extrusion.

1.4.SFS Materials, Connectors, And Manufacturing Techniques

Textiles that can respond to a broad range of stimuli, including mechanical, chemical, electrical, magnetic, thermal, and optical stimuli, are known as SFSs. The degree of complexity found in implementation varies greatly and is dependent on manufacturing techniques, materials utilized, kinds of sensing devices employed, and the type of supporting electronics used. A developing interdisciplinary research area that relies on knowledge in textile, materials, electrical, electronic, mechanical, and computer engineering is paralleling the development of SFSs. As seen in the next section, SFSs were first made utilizing an adapted electronics or e-textiles method[8].

1.5.Electrodes, Connectors, And Interconnects

SFSs are impossible to deploy without the technologies that enable the transmission and utilization of sensed data. Other fabric circuit components, sensors, and/or data collection

circuits must be linked to fabric sensors. Table 2 shows some of the most frequent connectivity techniques that have been discovered in the research; they vary depending on the kind of sensor and the application. One of the most difficult problems for SFTs is connecting to data collection, which is complicated by the fact that each application has its unique set of requirements. For example, the criteria for sensor mechanical stability in a garment are very dissimilar from those for a fabric sensor used to monitor the environment on a bookcase.

Circuit components made of textile Miniaturized and encapsulated textile circuit components may be tailored to the fabric structure. Miniature off-the-shelf components may be stitched directly through into fabric's conductive patterns, or by utilizing holders, sockets, or sequins that can be connected to the fabric in a variety of ways. Sequins may be stitched into conductive thread lines, and holder leads can be soldered to something like a fabric FCB, which really is a companies and users fabric that has been pre-treated. The stitching tabs contribute just a few millimeters of resistance to the circuit.

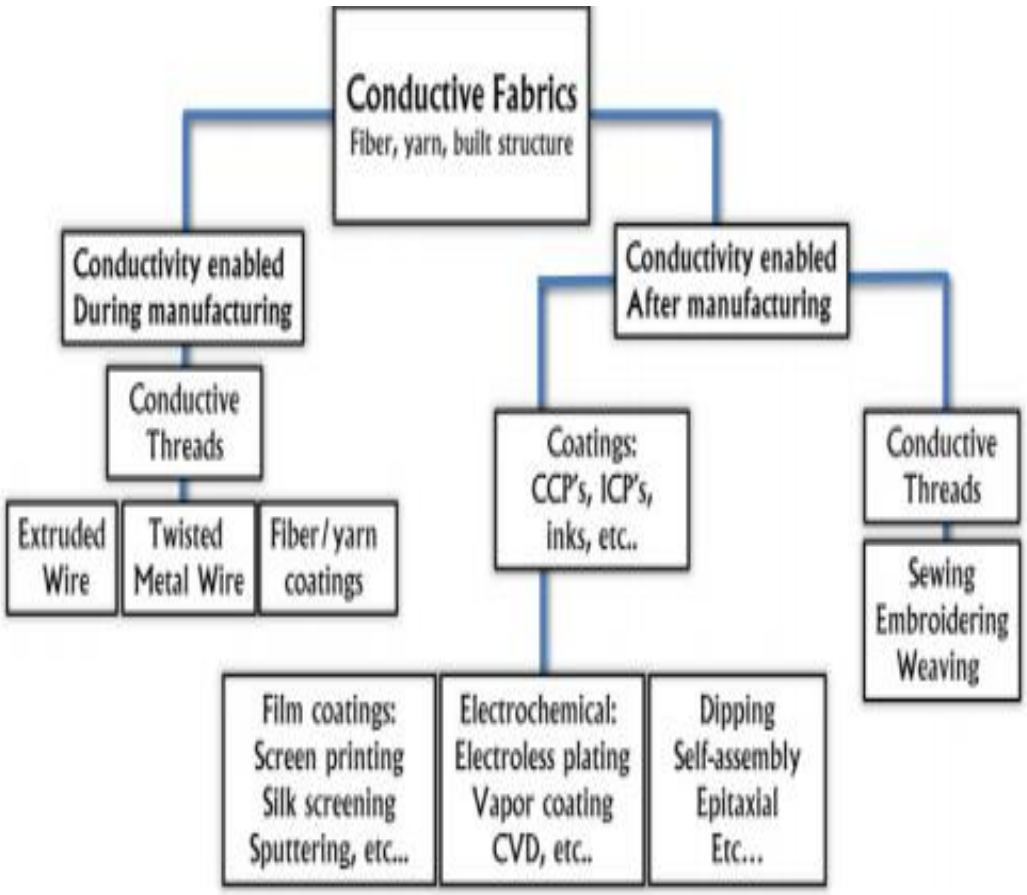

Figure 2: Techniques to enable conductivity in fabrics

Sewing thread fibers in patterns, potentially with numerous crossings, to obtain desired electrical characteristics may be used to make electronic components out of conductive thread. Numerous methods may be used to provide thread conductive characteristics before and after the thread production process, as shown by the figure 2. Each of these elements may be customized to create a circuit element with specific properties. The deposition of metal or conductive coating materials to the cloth surface is another popular method. Laminating methods, including those derived from conventional and flexible electronics, are also used.

1.6.Sensors in smart textiles

Fabric sensing ideas have been investigated in a number of capacities and for a wide range of applications. None standard fabric parts or components, on the other hand, have been identified as the most promising candidates for laying the groundwork for the sector. This section will demonstrate the most typical sensing methods found in fabric sensors using charts, figures, and summarizing tables.

1.7.Capacitive

Capacitive fabric sensors are most often used for pressure & tactile sensing. For use on textiles, a variety of patterns and materials have already been tested and prototyped. They vary from adapted electronics to inherently changed materials, but they all contain a dielectric element between two electrodes in common. E-textiles use ordinary capacitors that are connected to cloth utilizing customized techniques in adapted electronics. An adapted capacitor is usually placed on a frame that may be stitched, snapped, or glued to a fabric substrate before being connected to other devices or cables. Fabric capacitors may also be made using flexible conductive materials that serve as electrode plates and are insulated by different dielectrics and spacers[9].

1.8.Resistive

Some other method of making fabric pressure sensors is to find a relationship between pressure and electrical resistance. Integrated sensors may be made at any level of the fabric structure, including yarn, fiber, and coatings. The contact resistance of crossing conductive yarns changes as pressure is applied on a grid of intersecting embroidered conductive threads. By sensing the point where the resistances change, the location of the pressure applied to the fabric may be determined.

REVIEW OF LITERATURE

Amongst some of the numerous papers published in the area of smart fabric sensors, one titled "Smart fabric sensors and e-textile technologies: a critique" stands out. Lina M Castano and Alison B Flatau spoke about the situation. Textures are the newest silicon wafers, and they've sparked a lot of attention due to the possibility of useful devices and sensitive registration. Despite the fact that it is not a replacement for traditional hardware, this area has a market that is still in its early stages of development, since it lacks a standard set of methods or components. It became an integral part of the development of wearable technology. This article includes a review of advances required for the development of textures with combined utility, with a focus on sensor applications. Smart texture sensors (SFSs) are textures having detecting characteristics that are sensitive to a variety of physical and chemical changes, such as fluctuations in climate, pressing factor, power, and electrical current, amongst many others. At any level, detecting components may be merged into textures if the surrounding texture component is changed or sharpened[10].

Alison B Flatau studied the article offers an overview of current advances in the area of smart fabric sensor and electronic textile technology, which is constantly continuously developing. It covers the fundamental concepts and methods utilized in fabric sensor development, as well as the most frequently used materials and processes in electronic textiles. This article demonstrates how, depending on the degree of integration into the fabric platform, intrinsic and extrinsic changes to textile substrates may be used to generate sensing capabilities. Fabric sensors may be customized to detect force, pressure, chemicals, humidity, and temperature changes, according to the present research. Fabric techniques' materials, connections, fabric circuits, interconnects, encapsulation, and manufacturing techniques are more customizable and flexible than their traditional electronics equivalents. The results of this study indicate that by combining several kinds of textile-based functional components, a full smart fabric system may be created[1].

DISCUSSION

The textural pressure sensing capacitors are usually designed to match the work of art and to have a capacitance of Pico farads. The capacitive plate layers may range in thickness from microns to millimeters and can be calculated in a variety of ways depending on the intended use. Strain sensing components have a much higher maximum strain rate than conventional components and can adapt to any surface. The range of applicability for any kind of texture sensor is unmistakably determined by the motive for the application, as well as the mathematical and mechanical requirements. The affectability of such sensors will, for the most part, be determined by the composite structure's flexibility, temperature, and wetness. Other texture sensors include those with fine optic filaments that are sensitive to synthetic chemicals and gases, as well as those sensitive to environmental variations. All adaptable macro electronics advances, such as flexible presents, OLEDS, MEMS, texture photoelectric and energy collecting devices, and others, substantially complement SFTs.

CONCLUSION

The many layers of structure used in the design of texture-based sensors have been discussed, ranging from the inborn level with dynamic filaments to the outer level with discrete electrical segments connected to textures. Intrinsically conductive polymers and doped polymer matrix composites may be used to create natural detecting components. Outward detecting components, such as discrete units or coatings, may be constructed by modifying fundamental texture units to give them detecting characteristics such as optical, resistive, or capacitive, to name a few. Connectors, interconnects, and cathodes are determined by the same kind of sensor, mechanical requirements, and intended use. Every interface configuration is different and almost unique. Material hardware is possible thanks to techniques that have been tailored to textures. Ideas that combine commonplace devices with large-area hardware are critical to the development of hardware on materials. In any case, vigor is enhanced by reducing the adaptability of texture components, such as via shaping and embodying processes. Protective techniques are often confined tactics used from the textile business, but associations are frequently adapted from commonplace devices.

INTRODUCTION

The lives and activities of many individuals in Mazi have been coincided with complex socio-political events. Sometimes, it is known that they were at the forefront of that serious process and change, influencing the turbulent problems and contradictions of the period, the dangerous sins and sharp turns. Abulfath Abdullah Bahodirkhan ibn Iskandarkhan ibn Janibek sultan ibn Khojagum sultan ibn Abulhairkhan, who lived in the second half of the 16th century and was able to unite DashtiKipchak, Movarounnahr, Khorezm and Khorasan into a single state, is one of such historical figures. This article covers the political activities of Abulfath Abdullah Bahodirkhan, a talented politician and commander, statesman, creator and patron of science, based on information from historical written sources.

MATERIALS AND METHODS

Abdullah Khan II, who took advantage of the wars between the independent estates and the great nobility against them, gradually began to unite the lands of Movarounnahr and Khorasan under his rule. His actions were actively supported by the local sheikhs, Hodja Islam and his son HodjaSa'd. [Turaev, 2007: 70-75]. In 1561, Abdullah Khan II severed ties with his uncle Pirmuhammad and proclaimed his father, Alexander Sultan (1561-1583) khan. In fact, Iskandar was a khan in the name of Sultan and did not interfere in the management of the country, the power was in the hands of Abdullah Khan II. After the death of Alexander Sultan in 1583,

Abdullah Khan II was declared the official khan. [Eshov, 2012: 255]. Thus, in the second half of the 16th century, Abdullah Khan entered the political arena in the context of modern Uzbekistan in a complex historical context. Meanwhile, Hafiz Tanish Bukhari states in his work "Abdullanoma" ("Sharafnomai-shohi") that "the lands from the border of Kashgar region to Khorezm and from the border of DashtiKipchak to the foothills of Kandahar, all Movrounnahr, Khorasan, Turkestan and Khorezm)". [Bukhari, p.169]. In addition, the great orientalist W. W. Barthold said, "Abdullah II's reign was a rare event, and although he established his rule on the basis of cruelty and military force, not only the whole of Movrounnahr, rather, he was able to unite Khorasan and Khorezm and establish a strong state" [Bartold, 1963: 269], in another collection, the Muslim centralized state agreed with pure paganism [Bartold,1963:100]. Thus, in the second half of the 16th century, Movarounnahr entered the arena of political struggle and ruled the Bukhara throne for almost 41 years.

1. 1551 - 1557, the period of Abdullah Khan II's struggle for power;

2. 1557 - 1561, the struggle for the throne of the Bukhara Khanate and its conquest;

3. 1561 - 1578 - unification of Movarounnahr and centralization of power;

4. The years 1578-1595 were marked by the establishment of a centralized state in Central Asia [Sultonova, 2005:37-38].

Relying on the entire Uzbek tribes, the settled population, the Juyborkhojas and all the clergy, and all his followers, Abdullah II was promoted to khan, that is, when he was enthroned in white felt according to the old Turkic-Uzbek legal tradition, the ends of felt were as large as the customs of Turkic peoples demanded. Not the well-known chiefs of the tribes, rather, the centralization of the state, held by priests who were interested in strengthening discipline in it, meant that there were always religious scholars before it. After establishing a centralized state, Abdullah Khan conquered Badakhshan in 1584, Herat in 1588, Khorezm three times in 1593-94, and Khazarasp in 1595-96. Therefore, a strong centralized state was formed, and economic, political and political relations were re-established in all respects, from Kashgar to the Aral and Caspian coasts, from Turkestan and Sayram to the eastern part of Khorasan. At this point, if we briefly dwell on the personality of this Shaybani sultan Abdullah Khan, we will see that all the qualities of the rulers of the Middle East were embodied. He knew the history of his time as a skilled politician because he adhered to the idea of creating a centralized state. The fact that he chooses not to be harsh and shameless on this path is emphasized in the literature as the "Blood and Iron" path. [Mukimov, 2008:36-37].

There could be no other way than this one. It is true that, despite nearly two decades of struggle with its enemies in the political arena, many generations of Shaybanis perished, and many of their descendants perished during the Shaybanid state's policy of unification does not mean that the internal conflicts in the state are completely over. [Ziyo, 2001:241]. At the end of the years of his reign, the vassals of Abdullah Khan II began to strike him with treacherous blows. In particular, as a result of a sudden attack by his former ally, the Kazakh khan Tavakkal, behind treason, his troops were defeated and they invaded the property of Bukhara. In the south, Iranian troops are pushing the Uzbeks out of Khorasan. After his death, Khorezm regained its independence. His only son, Abdulmomin, was assassinated as a result of a threat-based policy that lasted only six months of his rule. [Mukimov, 2007: 79-80]. Indeed, Abdullah Khan P's policy of unification, which he pursued on the basis of strictness, is almost identical to the historical process in the political development of the countries of the world (emphasis from the author).

In this sense, the period of Abdullah Khan II's rule of the Bukhara Khanate was limited by the formation of the central state power, its success by military campaigns and the expansion of state

borders. People close to the khan were appointed to each provincial administration. It was a major success, to have the necessary economic results. In the years following Ubaydullah's death, while the khan had only a provincial status, Abdullah II became the real ruler of the whole state. [Ziyo, 2001:32]. Abdullah Khan II sought to centralize the country economically as well as politically and territorially. The minting of coins by each governor on his own behalf had a negative effect on the depreciation of the currency and domestic and foreign trade. The monetary reform carried out by Abdullah Khan II strengthened his position in the central government. In addition, special attention was paid to irrigation. Many reforms have been carried out in the fields of culture and architecture. Abdullah Khan carried out a number of reforms to regulate the affairs of state, the implementation of Sharia law, and the strengthening of law and order. In 1581, for example, he reformed the currency "because he was benevolent to the people entrusted to him by God" and After making it clear, he commanded that he be kind to the people entrusted to him by God: “Let them clean the gold without mixing anything else, and let the money be a shekel (1.37 dirhams of gold).

During this period, that is, in the 16th and 19th centuries, they used to weigh 4.8, sometimes 5 grams, and weigh 6 coins, and uproot the foundations of fraud.” [Bukhari, p.52-53] the severe punishment of those who set it shows that the legal system of that period was also well established. This monetary reform, carried out by Abdullah Khan II in public life, played a major role and had a significant impact on the development of the country's economy. According to another source, Hafiz Tanish al-Bukhari wrote that Abdullah Khan II started minting gold coins, Abdullah Khan made sure that other low-value ores were not added to the gold coin. [Akhmedov, 1999:4-5]. This means that Abdullah Khan II ordered the minting of gold coins for the development of the economy in the state, and tightened control over it so that it would not be counterfeited, thus ensuring the stability of the state. During the monetary reform carried out by Abdullah Khan II, it was ensured that the money issued in Bukhara was put into equal circulation. [Davidovich, 1951:108-113].

This not only contributed to the further centralization of state power, but also increased the socio-political significance of Bukhara. At the same time, the implementation of this policy was facilitated by the greater centralization of the state and the greater centralization of the khan's power during the reign of Abdullah II. The increase in revenues to the state treasury from minting money has helped to expand and regulate trade.

RESULTS AND DISCUSSIONS

Abdullah Khan II was a skilled politician, a brave soldier, a head of state who built at his own expense many social structures, 1001 rabots and cisterns (closed reservoirs) (this will be discussed in the next separate paragraphs). His whole life was spent on the battlefields for the establishment of this centralized state, and Hafiz Tanish's "SharofnomaiShahiy" can rightly be called "Abdullah's War". The idea of a centralized state has become part of universal values and has been valued in political history. Therefore, his work in this area is positive, but in the way of achieving this, we can be sure that he chose the path of "Blood and Iron". In the ninth chapter of Abulgazi'sShajarai Turk, we find reliable information about Khiva-Bukhara relations, Abdullah Khan's three trips to this state and its consequences. [Abulgazi, 1992:154]. He was an educated man, and according to H. Nisari, he wrote poems in Uzbek and Persian under the pseudonym "Honiy". [Niori, 1992:45]. The poetic letter of Abdullah Khan II to the governor of Samarkand Juvonmardalikhan, written in Persian, is given in SiddiqhonHashmat'stazkira book "NomaiKhisravoniy": In this world, the dream of the "Khan" is always to go to the tomb of Shahizinda and become a slave. [Kattaev, 2003:27]. In the middle of the 16th century, during the reign of the Shaybanis, especially Abdullah Khan II, ambassadors often came and exchanged letters in order to establish diplomatic and trade relations with Russia, India, Turkey and Kashgar. In particular, when Abdullah Khan II was in Zaamin (Ikar reserve) in 1578, an “envoy

sent by Jalaliddin Muhammad Akbar, the king of India," came to him and discussed the question of defining the spheres of interaction in Khorasan and Iran. [Bukhari, 2000:119-120]. Especially during this period, after the annexation of the Kazan and Astrakhan khanates to the Moscow state, it became possible to establish direct contacts with Russia. In 1557, ambassadors were sent from Khiva and Bukhara to Russia to facilitate trade. The fact that in 1558 Jenkinson came to Bukhara as an ambassador of the Russian tsar Ivan IV, and during the reign of Abdullah in 1583 ambassadors came to the khan with valuable gifts and greetings shows that the relations of cooperation did not stop.

In general, the study revealed that by 1600, five ambassadors from Bukhara and twice from Khiva had visited Moscow, mainly to discuss trade. We can also see that there were regular exchanges of ambassadors between the Shaybanid state and Kashgar, including during the second period of Abdullah Khan, ambassadors headed by DostMirzoMirzoChuhra agha visited Kashgar.

CONCLUSION

Examining the life and work of Abdullah Khan II, who ruled the Uzbek statehood for a hundred years during the Shaybanid dynasty, we can summarize:

First of all, only Abdullah II, after our ancestor Amir Temur, had the honor and happiness to unite the whole country of Turkestan around a single flag, a single capital. This was directly achieved by his skillful and courageous military leadership, prudent policy, wisdom, skillful diplomacy, which raised the country's economy on the basis of the development of irrigated agriculture and handicrafts.

Secondly, although Abdullah II spent his life on horseback, in the heat of battle, he remained in the memory of our people, in our history, as an economic, cultural, in particular, patron of architecture, a great statesman and diplomat. That is, most of the 16th-century architectural monuments in Central Asia today were built during the reign of Abdullah II, and their number exceeds 1,000. These facilities, in particular, the construction of indoor markets and stalls (ToqiZargaron, ToqiSarrafon, ToqiKitabfurushon, etc.), hotels, baths [20. A.Sagdullaev, B.Aminov, U.Mavlanov, N.Norkulov, 2000-171], have improved trade, The Ottoman Turkish state, the Baburis of India, and the khanates of East Turkestan, in particular, sought to improve trade relations with Russia, thereby trying to strengthen the political position of their state.

Thirdly, Abdullah II is the only person after Amir Temur who was able to pursue a strict policy. In the second half of the 16th century, in Movarounnahr, Khorezm and Khorasan, ending the political turmoil and the struggle for the throne, the establishment of peace in the country and the unification of power under a single center allowed the khanate to improve various areas of production, such as textiles, architecture and ceramics.

ABSTRACT

The scientific article deals with the application of award symbols established during the Soviet era to the Uzbek SSR, as well as the history of awarding traditions in the Soviet years on the example of Fergana region. In particular, on the basis of the documents of the State Archives of Fergana region, it was reflected that each profession was gradually awarded. Also, a comparative analysis of the awarding of mothers with many children with orders and medals of various levels, the awarding of the honorary title of "Mother Heroine" and the development of appropriate recommendations.

KEYWORDS: *Award, Fergana Regional State Archive, Uzbek SSR, Supreme Soviet Presidium, Order, Medal, Honorary Title "Hero Mother", Orders And Medals Of The Soviet Government, Fund, Mothers With Many Children, Phalleristics.*

INTRODUCTION

If we look at the history of the reward system in Uzbekistan during the period from the establishment of Soviet power to independence (republics of the RSFSR (BSSR, XXSR, TASSR, 1917-1924; UzSSR within the USSR, 1924-1991)) Of course, the improvement of the reward system has played an important role in the development of each sector on the basis of a single dominant ideology - the communist idea.

It should be noted that the analysis of archival sources obtained during the study shows that the orders and medals created during the Soviet era, including the reward system, served the ideology of this historical period, the socio-political life of society, the interests of the socialist system.

The main findings and results

During the historical period from 1918 to 1991, 21 orders and 54 medals, 4 high-level and 15 honorary titles were established, which formed the basis of Soviet awards. The tradition of awarding honorary weapons and flags and awards is also widespread.

The Soviet-era reward system was first defined in legal documents and became an important part of the state ideology. In particular, Article 121 of the USSR Constitution delegates the right to

establish and present USSR orders and medals to the Presidium of the Supreme Soviet of the USSR (Presidium of the Supreme Soviet of the USSR) [1, 30]. Each order has its own level, and the Statute of the medal has been developed and established. These documents reflect the content of the award, the award, the order of wearing, privileges and other legal aspects. State awards were awarded to citizens of the Soviet Union, organizations, cities, regions, republics, as well as non-citizens of the Union.

In May 1936, the USSR MIQ and HSQ Resolution established the Document "General Rules on Orders of the USSR" (Общее положение об орденах СССР) [52]. This document was in force until 1979, and then in 1979 was adopted the Regulation "On the general rules of orders, medals and honorary titles of the USSR" (General position on orders, medals and honorary titles of the USSR). According to the Charter, "Soviet-era awards established in the first five years of the Civil War, the Great Patriotic War, as well as in the years of economic recovery and development symbolize the history of the Soviet state, the undeniable heroism and honorable work of various categories of the Soviet era." [53]. Beginning in 1938, a special order document was also issued to those awarded the order. Prior to that, the winners were awarded certificates of honor. The rules of wearing orders and medals were approved on March 28, 1980 by the Decree of the Presidium of the Supreme Soviet of the USSR.

As a result of the analysis of the documents related to this award system, it should be noted that the following state awards were in force during the Soviet era:

High-level honorary titles and badges:

1. The title of Hero of the Soviet Union (Hero of the Soviet Union), founded in 1934;

2. The title of Hero of Socialist Labor (Geroya Sotsialisticheskogo Truda), founded in 1938;

3. The title of "Hero City" (Gorod-Geroy), the title of "Kahramoni Qala" (Fortress-Hero), founded in 1965;

4. The title of "Mother Heroine" (Mat-Geroinya), founded in 1944.

In addition, a number of orders were established for heroism of the revolution, long service, protection of the socialist homeland, development of cooperation and friendship between peoples, strengthening peace and other services to the Soviet state and society:

1. The highest award of the USSR - the Order of Lenin (Order of Lenin), founded in 1930;

2. Order of the October Revolution (Order of Oktyabrskoy Revolyutsii), founded in 1967;

3. Order of the Red Banner of Labor (Order of Trudovogo Krasnogo Znameni), established in 1928;

4. Order of Friendship of Peoples (Order of Druzhby Narodov), established in 1972;

5. Order of the Badge of Honor (Order Znak Pocheta), established in 1935, after 1988 the name was changed to the Order of Honor (Honorary, Order Pocheta);

6. Order of Personal Courage ("Za lichnoe mujestvo"), established in 1988;

7. Order of Labor Glory (Order Trudovoy Slavy) 1st, 2nd, 3rd degree, established in 1974.

He was also awarded the following orders for his services in the defense of the socialist homeland and other military services:

1. Higher Military Award - Order of Victory (Pobeda), established in 1943;

2. Order of the Red Banner (Krasnogo Znameni), established in 1918, 1924;

3. Order of Suvorov 1st, 2nd, 3rd degree, established in 1942;

4. Order of Ushakov 1st and 2nd degree, established in 1944;

5. Kutuzov Order of the 1st, 2nd, 3rd degree, established in 1942, 1943;

6. Nakhimov Order of the 1st and 2nd degree, established in 1944;

7. Order of Bogdan Khmelnitsky 1st, 2nd, 3rd degree, established in 1943;

8. Order of Alexander Nevsky, founded in 1942;

9. Orders of the Patriotic War (Otechestvennoy voyny) 1st and 2nd degree, established in 1942;

10. Order of the Red Star (Krasnoy Zvezdy), founded in 1930;

11. Order of the 1st, 2nd, 3rd degree for services to the Fatherland in the Armed Forces of the USSR (Za slujbu Rodine v Voorujennykh Silax USSR), established in 1974;

12. Order of Glory (Slavy) 1st, 2nd, 3rd degree, founded in 1943;

Also to mothers for giving birth and raising at least 10-12 children in a family during the Soviet era:

1. Order of the Mother of Heroes (Mat-Geroinya), founded in 1944;

2. Order of Motherhood Glory (Materinskaya slava) 1st, 2nd, 3rd degree, established in 1944.

In the study of the subject is kept in the State Archives of Fergana region: 1124 fund - the Executive Committee of the Fergana Regional Council of Workers' Deputies. Council of People's Deputies (Executive Committee of the Fergana Regional Council of People's Deputies since 1978. Council of People's Deputies);

Fund 8 - Executive Committee of the Fergana City Council of Workers' Peasants and Deputies of the Red Army. Council of People's Deputies (Executive Committee of the Fergana City Council of Workers' and Krasnoyarsk Deputies since 1978. Council of People's Deputies);

Fund 731 - the Fergana Regional Council of the Society of Inventors and Rationalizers of Uzbekistan (Fergana Regional Council of the Uzbek Republican Council of Inventors and Rationalizers). The following volumes have been analyzed and new data that have not yet been studied have been put into scientific circulation and proved:

Decrees of the Presidium of the Supreme Soviet of the USSR on awarding orders and medals of the Presidium of the Supreme Soviet of the USSR to the heads of agriculture of the Uzbek SSR (1984);

Decrees of the Presidium of the Supreme Soviet of the USSR on the awarding of orders and medals of the USSR to the heads and workers of all branches of the Fergana region

Decrees of the Presidium of the Supreme Soviet of the USSR on the awarding of medals of the USSR (Decree of the Presidium of the Supreme Soviet of the USSR on the awarding of medals of the USSR) (1959-1964);

Decrees of the Presidium of the Supreme Soviet of the Uzbek SSR on the awarding of honorary diplomas to employees of all branches of the Fergana region*;*

Decrees of the Presidium of the Supreme Soviet of the USSR on conferring the honorary title of "Hero-Mother"

Decrees of the Presidium of the Supreme Soviet of the Uzbek SSR onawarding medals "Motherhood Glory" and "Motherhood Medal" in the districts of Fergana region

Decrees of the Presidium of the Supreme Soviet of the Uzbek SSR on awarding orders and medals to mothers with many children

Book of registration of orders and medals of the Supreme Soviet of the USSR (Kniga ucheta ordenov i medaley Verkhovnogo Soveta SSSR) (1950-1951);

Resolution of the Executive Committee on the awarding of medals "Veteran of Labor" (1968-1970, 1984, 1988);

List of recipients of the medal "30 years of victory in the Great Patriotic War of 1941-1945" (List of awarded medals "30 years of Victory in the Great Patriotic War of 1941-1945" (1975-1977);

Documents on awarding jubilee medals "40 years of victory in the Great Patriotic War" (Документыпонаграждениюу Jubilee medals "40 years of victory in the Great Patriotic War") (1985-1987);

Act on awarding medals "For glorious labor" in the Great Patriotic War of 1941-1945 in the districts of Fergana region (Act of awarding medals "For double labor" in the Great Patriotic War of 1941-1945 in the Fergana region)

During the period under study in all regions of the Uzbek SSR (Andijan, Bukhara, Jizzakh, Kashkadarya, Namangan, Samarkand, Syrdarya, Surkhandarya, Tashkent, Fergana, Khorezm regions, Tashkent and Karakalpak ASSR) a system of rewards was established. Implemented by Decrees and Resolutions of the Presidium of the Council. Awards with them are held regularly every month of the year:

Orders - Lenin, Red Banner (Krasnogo Znameni), 1st and 2nd degree Patriotic War (Otechestvennoy voynы 1, 2nd degree), Labor Red Flag (Trudovogo Krasnogo Znameni), Red Star (Krasnoy Zvezdы), Badge of Honor (Znak pocheta), Hero mother (Mat heroine) and Motherhood fame (Materinskaya slava);

Medals - "Sickle and hammer" (Serp i molot), "For Courage" (Za otvagu), "For Combat Services" (Za boevye zaslugi), "For glorious labor" (For labor doubles), "For example in labor" ”(Za trudovoe otlichie) and“ Onalik medali ”(Medal materinstva).

Also, among the documents confirming the winners were presented the Book of Heroes, the Book of Heroes, the Book of Orders and the Certificates of Medals. [2, 2].

In the Uzbek SSR and other allied republics, people awarded the 3rd degree "Hero of the Soviet Union", "Hero of Socialist Labor" and "Order of Glory" were provided with coupons, letterheads and created opportunities in a number of areas. For example, free tickets and tickets for rail, water, air or long-distance road transport, as well as intra-city transport and inter-district bus routes are provided. These opportunities were valid for 5 years [3, 19-20].

As a result of the analysis of archival data, the tradition of awarding the Order of Motherhood Glory and the Medal of Motherhood was widely practiced in all regions of the Uzbek SSR. Only at the meeting of the Presidium of the Supreme Soviet of the Soviet Socialist Republic of Uzbekistan in 1946, the Presidium of the Supreme Soviet of the CCCR on July 8, 1944 The report on the implementation of the Decree "On the establishment of the Order of Motherhood Glory and the Medal of Motherhood" [4, 9]. According to him, from 1944 to 1946, 153 mothers in the Uzbek SSR were awarded the honorary title of "Heroic Mother", 5300 were awarded the

Order of "Motherhood Glory", more than 16 thousand people were awarded the "Medal of Motherhood" [4, 10-11].

Or, according to the report of July 1, 1964, the number of mothers with many children awarded orders and medals in the territory of the Uzbek SSR was 54058, including 7127 - Andijan (agriculture), 1331 - Andijan (industry), 3922 - Bukhara, 4514 - Kashkadarya, 8183 - Samarkand, 3819 - Surkhandarya, 3608 - Syrdarya, 5840 - Tashkent (agriculture), 884 - Tashkent (industry), 5869 - Fergana (agriculture), 966 - Fergana (industry), 3103 - Khorezm, 1957 - Tashkent city executive committee, 2935 - Karakalpak ASSR [5, 125].

By the Decree of the Presidium of the Supreme Soviet of the USSR on May 24, 1979 361 people from all over the territory of the Uzbek SSR [6, 2-22], on December 6, 1979 649 people [6, 163-181], on December 7, 1979 280 people [6, 300- 316], on December 19, 1979, 304 [6, 282-299] mothers of many children were awarded the Order of the Hero Mother and honorary orders.

In Fergana region, as in all other regions, the awarding of orders and medals to mothers of many children has been held annually and on time since the establishment of the award [5, 123]. For example, below we will try to cite the statistical calculations of the winners on the basis of data stored in the State Archives of Fergana region, although not every year, but every month.

In particular, by the Decree of the Presidium of the Supreme Soviet of the USSR of August 7, 1954, 24 people were awarded the Order of "Motherhood Glory" (hereinafter the Order), 96 people were awarded the Medal of Motherhood (hereinafter the medal) [7, 3]. 198 with the Order of December, 953 with the medal [8, 48], 56 with the Order of 17 August 1963, 243 with the medal [9, 89], 101 with the Order of March 30, 1963, 378 with medals [9, 184], 35 with orders by the Decree of October 5, 1964, 112 with medals [5, 86], 410 with orders with the Decree of March 28, 1966, 1062 with medals [10, 1], 332 with the Order of September 9, 1966, 925 with the medal [11, 2], 326 with the Order with the Decree of October 21, 1966, 899 with the medal [11, 199-200], December 31, 1966 35 with the Order, 119 with the medal [12, 2], 436 with the Order with the Decree of March 24, 1967 1019 people with medals [13, 3], 450 people with medals by the Decree of May 31, 1967, 1050 people with medals [13, 1-2], 429 people with medals by the Decree of September 21, 1967, 1065 people with medals [14, 1-2], 429 with the Order by the Decree of January 30, 1968, 904 with the medal [15, 2], 345 with the Order by the Decree of November 1, 1968, 824 with the medal [16, 2], By the Decree of January 31, 1969, 369 people were awarded orders, 819 people were awarded medals [5, 2], 530 people were awarded medals by the Decree of August 15, 1969, 992 people were awarded medals [18, 1-2], by the Decree of May 21, 1969 601 with orders, 1272 with medals [19, 1-2], 485 with orders by the decree of November 4, 1969, 1049 with medals [20, 1-2], 574 with orders by the decree of May 13, 1970 , 1184 with medals [21, 2], 526 with orders by decree of June 26, 1970, 995 with medals [22, 1-2], 504 with the Order of October 7, 1970, 973 with the medal [23, 1-2], 644 with the Order of February 23, 1973, 904 with the medal [24, 2], with the Decree of September 27, 1973 379 orders, 602 medals [25, 1-2], 537 orders on the basis of the Decree of October 26, 1973, 767 medals [25, 100], 306 orders on the basis of the Decree of November 28, 1980, 638 with medals [26, 2], with 195 orders under the Decree of March 31, 1982, with 478 medals [27, 1-2], with the Order of January 31, 1986 with 118 orders, with 442 medals [28, 1] mothers with many children were awarded. In the first half of 1985, Fergana region awarded 2,097 awards,

including 47 honorary titles "Heroic Mother", 2,050 orders "Motherhood Glory" and "Motherhood Medal" [29, 2].

During the analysis of archival documents, we were convinced that the Order of "Glory of Motherhood" and the "Medal of Motherhood" were divided into different levels, which were also presented as follows:

- For mothers with 10 or more children - the honorary title of "Heroic Mother";

- To mothers with 9 children - the order "Glory of motherhood" of the 1st degree;

- To mothers with 8 children - the order "Glory of motherhood" of the 2nd degree;

- To mothers with 7 children - the order "Glory of motherhood" of the 3rd degree;

- To mothers with 6 children - the medal "Motherhood" of the 1st degree;

- For mothers with 5 children - Medal "Motherhood" of the 2nd degree [21, 6-8].

As a result of the above statistics and the study of additional archival materials, it can be said that in all regions of the country, including Fergana region, the rate of awarding orders and medals to mothers with many children has increased from year to year. For example, in the Fergana region, the number of mothers with many children awarded orders and medals was 15,818 in 1967, 17,057 in 1968, and 19,037 in 1969 [30, 19-20]. In the period from 1957 to 1969 in the Fergana region, the honorary title of "Heroic Mother" was awarded to 973 mothers with many children [30, 19].

In the Uzbek SSR, the heads of Soviet bodies, enterprises and organizations, as well as the public, have taken great care of mothers with many children, in addition to state benefits, to provide them with financial assistance. For example, the Standing Committees of the Health and Welfare Councils, together with the staff of the Women's Councils, pay close attention to the study of housing conditions, the medical examination of mothers with many children and the health of children by health workers. Many were assisted in home renovations, new housing allocations, and fuel supply. Children of mothers with many children are primarily provided with boarding schools and kindergartens. In cities, collective farms, and state farms, the dairy kitchen was open free of charge to children.

During the Soviet years, the issue of employment of mothers with many children in Uzbekistan, the creation of all economic conditions for them was also under control. For example, according to the archives, L.Abdullaeva, the owner of the title "Hero Mother" with ten children, worked in the Fergana windmill factory and organized a public campaign in the women's council of the factory to promote communist ideology [30, 93].

Also in Kokand, H. Abdurahmanova was the mother of eleven children, as well as the secretary of the mahalla committee and worked on a community basis. Thanks to his active propaganda work, the residents of the mahalla collected 7 tons of raw cotton in the 1970 season and achieved a significant result.

A.Sultanova, who lives in Leningrad district, is also a mother of eight children, has worked as a school teacher for a long time and has achieved high results in the preparation of silkworms and cocoons. He was awarded the State Prize for the introduction of high-performance silkworm rearing, and the title of "Hero of Socialist Labor" for high yields of cocoons. He even served as a member of the Third All-Union Congress of Collective Farmers in Moscow [30, 94].

It can be said that hundreds of such "Heroic Mothers" have been found in the Uzbek SSR, among them many doctors, teachers, cotton growers, cattle breeders and other specialists of the national

economy. Mothers of many children worked as deputies of regional, city, district, village and township councils, and actively participated in the activities of standing committees and public amateur organizations of workers.

- It should be noted that in the study of the reward system of the Uzbek SSR in the Soviet years, the role of the USSR state awards, certificates of honor is invaluable. In particular, by the Decrees and Resolutions of the Presidium of the Supreme Soviet of the USSR, awarding events were held in the allied republics, including the Uzbek SSR, in the political, socio-economic and cultural spheres.
- In the Soviet years, the recipients of the USSR state awards received their awards in a solemn manner on the days of their professional holiday. For example, employees of the chemical industry were awarded on "Chemists' Day", railway transport workers on "Railwaymen's Day", workers of construction companies on "Builders' Day", traders on "Merchants' Day" [31, 2].
- For example, on the basis of the Decree of the Presidium of the Supreme Soviet of the USSR of February 12, 1948, on September 1 of each year, public educators, leaders, teachers were awarded USSR state awards for many years of service and selfless work. In particular, based on the level of his long-term work, the following awards were presented:

- 10-14 years of work - the medal "For exemplary work";
- 15-19 years of work - the medal "For Shavkatli Mehnati";
- 20-24 years of work - the order "Badge of Honor";
- 25-29 years of work - the order "Red Banner of Labor";
- 30 and more works - awarded the Order of Lenin [32, 6-10].

Also, in accordance with the Decree of the Presidium of the Supreme Soviet of the USSR of October 23, 1978, 92 health and medical workers in the Uzbek SSR were awarded USSR state awards ("Red Banner of Labor", "Badge of Honor" and "For Exemplary Labor" and "For Meritorious Labor". ”Medal) [33. 107-110].

Also, in accordance with the Decree of the Presidium of June 6, 1984, more than 300 agricultural leaders in the Uzbek SSR received state awards of the USSR ("Lenin", "October Revolution", "Red Banner of Labor", "Badge of Honor", "Friendship of Peoples", "Labor"). He was awarded the Order of "Glory" and the medal "For Meritorious Labor", "For Exemplary Labor" [34, 101-115].

Consequently, the awarding of state badges of the USSR was carried out in a solemn manner on a large scale in all regions of Uzbekistan. Analyzing the example of Fergana region among the regions of the republic, we come across lists of awards through a lot of statistics in the archives. For example, in the Fergana region, pickers who achieved good results in the socialist competition in the 1955 cotton harvest and set a special example were awarded certificates of honor of the Supreme Soviet of the Uzbek SSR. For example, Buvayda - 48, Akhunboboev - 16, Baghdad - 13, Fergana city - 3, Kirov - 12, Kaganovich - 2, Kuva - 10, Vodil - 1, Quybishev - 4, Toshloq - 11, Polotov - 19, Yazyavon - 9 , Altiyarik - 7, Frunze district - 27 representatives were awarded [35, 2-3].

Also, by the Decree of the Presidium of the Supreme Soviet of the USSR of August 30, 1960, 2 residents of Fergana region were awarded the Order of Lenin, 15 the Order of the Red Banner of Labor, 25 the Order of the Badge of Honor, 64 the Medal for Shavkatli Mehnati [36, 16].

By the Decree of March 1, 1965, 1186 award badges were sent to the Fergana region and handed over to their owners. In particular, 39 people were awarded the Order of Lenin, 136 the Order of

the Red Banner of Labor, 295 the Order of the Badge of Honor, 384 the Medal for Shavkatli Mehnati, and 332 the Medal for Exemplary Labor [37, 6]. The decree also includes a list of honorary titles: 43 "Honored Cotton Grower", 7 "Honored Agronomist", 3 "Honored Cattleman", 5 "Honored Irrigator", 17 people "Honored" mechanist ", 2 people were awarded the honorary title of" Honored basement worker "[37, 6].

By the Decrees of the Presidium of the Supreme Soviet of the USSR of December 31, 1966 and January 14, 1967, a group of our compatriots received a number of state awards of the USSR. In particular, "Lenin" - 1 person, "Red Banner of Labor" - 1 person, 3 people with the Order "Badge of Honor", 2 people with the medal "For Shavkatli Mehnati", 5 people with the medal "For Exemplary Labor" [38, 17], by the Decree of February 13, 1967, 44 people, including "Lenin" - 2 people, "Red Banner of Labor" - 4 people, 14 people with the Order "Badge of Honor", 11 people with the medal "For Glorious Labor", " 13 people with the medal "For exemplary work" [38, 1-3], 2741 people from Fergana region according to the Decree of August 12, 1971, including the title of "Hero of Socialist Labor" - 13 people, "Lenin" - 99 people, "October Revolution "- 129 people," Red Banner of Labor "- 704 people, 851 people with the" Badge of Honor "orders, 408 people with the" For Meritorious Labor "medal, 550 people with the" For Exemplary Labor "medal [31, 1-2], In accordance with the Decree of December 14, 1972, "Lenin" - 43 people, "Red Banner of Labor" - 447 people, "Badge of Honor" - 382 people, "Shavkatli Mehnati Uchun" medal - 199 people, "Mehnatda Orn Konsatgani" medal - 212 people. [39, 1-6], according to the Decree of December 25, 1976, 1449 people, including "Lenin" - 34 people, "October Revolution" - 61 people, "Red Banner of Labor" - 217 people, "Badge of Honor" - 288 "Labor Glory" 2nd degree - 11 people, "Labor Glory" 3rd level - 356 people, as well as 247 people with the medal "For Meritorious Labor", 245 people with the medal "For Exemplary Labor" [40, 285], In accordance with the Decree of May 30, 1977 and June 1-10, 42 people from Fergana region, including "October Revolution" - 1 person, "Red Banner of Labor" - 8 people, "Badge of Honor" - 13 people, "Labor Glory" - 3 levels - 8 people, as well as 7 people with the medal "For Meritorious Labor", 5 people with the medal "For Exemplary Labor" [41, 56], 1977 In accordance with the Decree of May 17-30, 140 people were awarded "Lenin" - 2 people, "October Revolution" - 2 people, "Red Banner of Labor" - 29 people, "Badge of Honor" - 31 people, "Labor Glory" for services in the field of agriculture. Level 3 - 24 people, as well as 26 people with the medal "For Shavkatli Mehnati", 26 people with the medal "For exemplary work" [41, 57], 267 people from Fergana region in accordance with the Decree of May 12-18, 1977, including Lenin "- 1 person," October Revolution "- 2 people," Red Banner of Labor "- 45 people," Badge of Honor "- 67 people," Labor Glory "level 3 - 53 people, as well as with the medal" For Glorious Labor " 51 people were awarded the medal "For example in labor" and 48 people were awarded [41, 58].

In accordance with the Decree of the Presidium of the Supreme Soviet of the USSR of January 18, 1974 "On the establishment of the medal" Labor Veteran "in Fergana region, 728 people were awarded the medal" Veteran of Labor "by the Executive Committee of People's Deputies of Fergana region. In particular, 104 people from Fergana, 232 from Quvasoy, 23 from Margilan, 123 from Toshloqsay, 83 from Oltiariq, 100 from Kirguli and 63 from Fergana districts were awarded this medal [42, 1-3]. In 1988, 1,731 people were awarded this medal [43, 1].

By the Decree of the Presidium of the Supreme Soviet of the USSR dated December 14, 1972, the First Secretary of the Fergana Regional Committee of the Communist Party of Uzbekistan Shamsudinov Fahriddin Shamsudinovich was awarded the title of "Hero of Socialist Labor", the Order of Lenin and the Gold Medal "Sickle and Hammer" [38, 92]. H.Arzikulova, F.Artikova, U.Bekniyozov, E.Jumaev, H.Ishonov, N.Komarov, M.Marahimov, K.Mirzaev, U.Nurullaev, A.Rakhmonov, S.Sidikov, S Tairov, Z. Tasheva, A. Khudaiberganov were also awarded [38, 94-95]. In 1967, by the decision of the Executive Committee of the Fergana region of Workers'

Deputies, 54 people were awarded the medal "For saving the drowning" for bravery and courage in saving lives, in times of chronic drought [3, 1-3].

During the Soviet era, state award badges were also presented to cities and districts. For example, in 1967 a ceremony of awarding the Order of Lenin was held at the Lenin collective farm in the Pop district of Fergana region. The fact that the Order of Lenin was the most inspiring symbol of the aspirations for the victory of communism at that time, as well as a beacon of new victories in the party leadership, was applauded by individuals and organizations who sincerely served and believed in the Soviet state system [3, 50].

This can be explained by the fact that in Uzbekistan during this period, a lot of attention was paid to the system of rewards, including the awarding of small businesses. For example, on May 22, 1971, the Presidium of the Supreme Soviet of the Uzbek SSR appointed a number of Fergana residents who contributed to the production and development of rabbit breeding, meat and skin - M. Ibragimova, U. Iminova, A. Mahmudov, S. Mirzaev, N. Mikhailov, I. .Sarmanov, B.Esonmirzaev were awarded with honorary diplomas [44, 157].

The tradition of commemorating and celebrating the 10th, 20th, 30th and 40th anniversaries after the victory in World War II was widespread in the Soviet Union, including Uzbekistan. In this regard, jubilee, commemorative and commemorative medals established by the Supreme Soviet of the USSR in honor of the great victory were awarded to all regions of Uzbekistan.

For example, on the basis of the task assigned to the Presidium of the Supreme Soviet of the USSR, in 1965, 400 medals "20 years of victory in the Great Patriotic War of 1941-1945" were sent to Fergana region. The medal was awarded to former partisans, as well as to those who received the medal "For Victory over Germany in the Great Patriotic War of 1941-1945" and a number of others who served in the USSR military and set an example behind the front [38, 37-38]. Also, in 1965, 53 people from Margilan [38, 39], 700 people from Quvasoy [38, 40], 1800 people from Kirov [38, 41], 2269 people from Leningrad [38, 42], 1901 people from Uzbekistan district [38, 43]. The proposal and the list to award the medal "20th anniversary of the victory in the Great Patriotic War of 1941-1945" were sent to the Supreme Soviet of the USSR and preserved in archival documents. As a result of the analysis of archival data, it should be noted that in 1967 alone, 900 medals were sent to Fergana region entitled "20th anniversary of the victory in the Great Patriotic War of 1941-1945." Of these, 780 were presented to their owners and the rest were stored in the prize warehouse [38, 24].

In 1975-1977, 1292 people from Fergana region were awarded the commemorative medal dedicated to the 30th anniversary of the victory in the Great Patriotic War of 1941-1945. The medal bears the inscription "Participant of the Labor Front" [45, 1]. A large amount of this medal was sent to the population of Kokand, which numbered 801 [45, 179].

In 1985-1987, a commemorative medal dedicated to the 40th anniversary of the victory in the Great Patriotic War of 1941-1945 was established [46, 1]. with medals "For Victory over Germany in the Great Patriotic War" and "For Victory over Japan", as well as orders of the USSR during the Great Patriotic War and medals for "heroic work in the Great Patriotic War of 1941-1945" in defense of cities. presented to awarded front and frontline workers [47, 132]. The medals were presented with the inscription "War veteran" or "Labor front participant".

According to the archives, in 1986, a total of 870 medals were requested in Fergana region, 70 of which were awarded to registered residents. [47, 114,120].

In addition, all regions of Uzbekistan, such as the Allied republics, were awarded medals and other awards "For the victory over Germany in the Great Patriotic War of 1941-1945" [38, 27]. For example, in all regions of Uzbekistan, the people who contributed to the victory in World War II and worked hard were awarded the medal "For valorous work in the Great Patriotic War of 1941-1945" (For hard work in the Great Patriotic War of 1941-1945). In a letter from A. Muminov, Chairman of the Presidium of the Supreme Soviet of the USSR, to B. Usmonkhodjaev, Chairman of the Executive Committee of the Fergana Regional Soviet of Workers' Deputies, in 1946, [48, 5] meant that there was a serious focus on rewarding events.

The life and work of each recipient of state awards in the territory of Uzbekistan and the process of awarding are widely covered on radio and television, as well as in the press, newspapers ("Fergana Haqiqati", "Kommuna" in Fergana region) [31, 2] .

The Resolution of the Presidium of the Supreme Soviet of the Soviet Socialist Republic of Uzbekistan was published on September 16, 1986 "On the order of publication of materials on the awarding of state awards" [47, 24-25]. According to it, on behalf of the Presidium of the Supreme Soviet of the USSR to award the Presidium of the Supreme Soviet of the Uzbek SSR with medals "For special services in maintaining public order", "For rescuing the drowning", "For courage in fire" and "Motherhood Glory" and "Motherhood Medal" Decrees of the Presidium of the Supreme Soviet of the Uzbek SSR, as well as enterprises, associations, institutions, organizations, state farms, collective farms, creative teams, military units (units, associations, unions and military educational institutions), regions, districts, cities, villages, auls, separate Decrees on awarding individuals or groups of workers with honorary diplomas of the Presidium of the Supreme Soviet of the Uzbek SSR and decrees on awarding honorary titles to citizens and creative communities of Uzbekistan will be published in the Bulletin of the Supreme Soviet of the Uzbek SSR and republican newspapers. (“Vedomostyax Verkhovnogo Soveta Uzbekskoy SSR”).

Reports on awarding mothers with many children with the medals "Motherhood Glory" (in the form of a list of winners) and "Medal of Motherhood" (in the form of an annual) will be published in city and district newspapers under the headings "Presidium of the Supreme Soviet of the Uzbek SSR".

Decrees of the Presidium of the Supreme Soviet of the Uzbek SSR on awarding honorary titles of the Uzbek SSR and awarding individual citizens or groups of workers with honorary diplomas of the Presidium of the Supreme Soviet of the Uzbek SSR are usually published in republican newspapers in the form of chronicles or lists.

CONCLUSION

Announcements of awarding citizens with the medal "Veteran of Labor" were published in local newspapers in the form of a short chronicle, and the decrees were published in full in the labor collectives where the awardees work.

In conclusion, a lot of new information was obtained on the topic of research based on archival sources, and a number of scientific results were obtained. In particular, new, not yet scientifically circulated historical and statistical data were identified and compared using archival data. This is explained by the fact that the awards, established during the Soviet era, have been implemented in Uzbekistan, including in the Fergana region, where a large part of the population of the valley, especially the "Heroic Mothers" came from and were awarded. Also, the status of implementation of state award symbols was studied chronologically. Along with a number of achievements, it was determined that a number of tasks needed to be accomplished:

- Consolidation of a special fund in the State Archives of Fergana region called the system of rewards in the regions of the Uzbek SSR;

- Creation of an illustrative manual "Tradition of awards of the Uzbek SSR (in the regions)", which distinguishes the awards of the Soviet era, the honorary title "Hero-Mother" and other awards;

- Opening a separate section in the existing large museums of Fergana region, dedicated to the awards won by the residents of Fergana region;

- Study and scientific circulation of award documents in the archives of foreign countries (Russian Federation, CIS) in the funds belonging to the Uzbek SSR;

- Development of a more detailed study of the system of rewards and historical research in the Uzbek SSR in the Soviet years (based on regional studies).

A DISCUSSION OF DIABETES, ANTIOXIDANTS AND OXIDATIVE STRESS

Ms Namrata Arya*

*SBAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: namrata.sobas@sanskriti.edu.in

ABSTRACT

Oxidative stress seems to have a significant role in the development of both forms of diabetes mellitus, according to a growing body of data from both potential therapeutic investigations. In diabetes, glucose oxidation, non-enzymatic glycation of proteins, and subsequent oxidative breakdown of fasting blood glucose proteins produce a disproportionate amount of free radicals. Damage to cellular organelles and processes, oxidative stress, and the development of metabolic syndrome may all result from abnormally high amounts of free radicals and a concurrent decrease in antioxidant defense systems. Those oxidative stress effects may contribute to the growth of diabetic complications. This review discusses changes in oxidative stress biomarkers such as superoxide dismutase, catalase, glutathione reductase, glutathione peroxidase, glutathione levels, vitamin supplements, lipid peroxidation, nitrite intensity, non-enzymatic glycosylated proteins, and hyperglycemia in diabetes, as well as their implications. The impacts of various conventional and alternative medicines upon those biomarkers are investigated in vivo. In order to broaden therapeutic approaches, more research is needed on the link involving free radicals, diabetes, and its complications, as well as the processes through which enhanced oxidative stress promotes the development of diabetic problems.

KEYWORDS:*Antioxidants, Catalase, Type 1 Diabetes Mellitus, Glutathione Peroxidase, And Oxidative Stress.*

1. INTRODUCTION

Diabetes mellitus is a complex disease high blood glucose levels and insufficient endogenous insulin production or activity. Although the cause of this illness is unknown, it has been linked to viral infection, autoimmune disease, and environmental factors. While exogenous insulin as well as other medicines may help manage many aspects of diabetes, problems plaguing the vascular system, kidney, retina, lens, peripheral nerves, and skin are frequent and can be very expensive in terms of lifespan and standard of living. Increased oxidative stress is a well-known contributor to the incidence and progression of diabetes, as well as its consequences[1]. Diabetes is often accompanied by significant in free radical generation or a reduction in antioxidant defenses. The activation of transcription factors, advanced glycated end products, and protein kinase C are

some of the mechanisms through which increased oxidative stress contributes to diabetes complications. This review focuses on current diabetes and medication intervention experimental investigations conducted in the setting of in vivo assay systems. In addition, there are many in vitro tests and clinical trials that need their own study[2].

1.1.Free Radicals And Diabetes Complications: An Introduction

Free radicals in excess cause damage to cellular proteins, membrane lipids, and nucleic acids, leading to cell death. The production among these reactive oxygen-free radicals has been linked to a number of processes. The primary source of free radicals is thought to be glucose oxidation. In its enediol state, glucose is oxidized to an enediol radical anion, which is then transformed into reactive keto aldehydes and superoxide anion radicals in a transition-metal dependent process. In the presence of transition metals, superoxide anion radicals dismutase to hydrogen peroxide, which, if not destroyed by catalase or glutathione peroxidase, may result in the formation of highly dangerous hydroxyl radicals. Superoxide anion radicals may also generate reactive peroxynitrite radicals when they react using nitric oxide. Hyperglycemia also promotes lipid peroxidation of low-density lipoprotein through a superoxide-dependent mechanism, which results in the production of free radicals[3]. The interaction of glucose with proteins, which results in the production of an Amadori product and subsequently advanced glycation end products, is another major source of free electrons in diabetes.

1.2.Antioxidants: A Quick Guide

While hyperglycemia produces free radicals, this even compromises the endogenous antioxidant defense mechanism in a variety of ways throughout diabetes. Enzymatic and non-enzymatic methods are used in antioxidant defense systems. Vitamins A, C, and E, glutathione, and the enzymes superoxide dismutase, catalase, glutathione peroxidase, and glutathione reductase are all examples of antioxidants. Lipoic acid, blended carotenoids, coenzyme, various bioflavonoids, antioxidant minerals, and cofactors are among the other antioxidants. They act together to combat various kinds of free radicals in a synergistic manner. Vitamin E inhibits lipid peroxidation propagation; vitamin C inhibits hydro peroxide formation when combined with vitamin E; metal functionalization agents, such as penicillamine, bind transition metals entangled in some lipid peroxidation reactions and inhibit Fenton and Haber-Weiss-type public reaction; vitamins A and E scavenge reactive oxygen species[4].

1.3.In Vivo Diabetes Research Using Biomarkers Of Oxidative Stress

Peroxidation of Lipids both directly and via degradation to extremely hazardous hydroxyl radicals, hydro peroxides have harmful effects on cells. They could also combine with transition metals like iron or copper to produce stable aldehydes like malondialdehydes, which can harm cell membranes. Peroxyl radicals may deplete hydrogen in lipids, resulting in hydro peroxides, which promote the free-radical pathway even further. Inducing diabetes in rats with streptozotocin or alloxan causes a uniform rise in thiobarbituric acid reactive compounds, which is an indirect indication of increased free-radical generation. Reducing hydroxyl radical production would be an effective way to decrease hydroxyl-induced damage, and many substances have been tried as antioxidants in diabetic animals with different degrees of effectiveness. Treatment with nicotinamide, boldine, melatonin, aspirin, L-arginine or sodium nitroprusside, probucol, -lipoic acid, aminoguanidine, captopril, enalapril, or nitecapone, for example, may reduce the rise in TBARS associated with diabetes if administered before or soon after the diabetogen. Treatment with a combination of vitamins C, E, and gemfibrozil, probucol, and vitamin E also might reverse the development of TBARS after diabetes has been established. Plasma lipids and hemostatic risk factors are reduced by dietary supplementation with -lipoic acid, evening primrose oil, or sunflower oil[5].

1.4.Glutathione Levels

Reduced glutathione is a major intracellular redox buffer that may approach concentrations up to 10 mM. Glutathione functions as a direct free-radical scavenger, as a cosubstrate for glutathione peroxidase activity, and as a cofactor for many enzymes, and forms conjugates in endo- and xenobiotic reactions. Levels of glutathione are reported to be normalized by vanadyl, dehydroepiandrosterone, oil of Eruca sativa seeds, nicotinamide, L-arginine or nitroprusside, melatonin, and melatonin plus desferrioxamine when these antioxidants are given prior to or at the same time as the diabetogen[6].

1.5.Peroxidase And Reductase Of Glutathione

Proteolytic enzymes present in the cytoplasm, mitochondria, and nucleus are glutathione peroxidase and reductase. Glutathione peroxidase uses reduced glutathione as a hydrogen donor to convert hydrogen peroxide to water. Glutathione reductase uses the cofactor NADPH produced by glucose 6-phosphate dehydrogenase to recycle glutathione disulfide again to glutathione. In diabetic mice, the activity of glutathione reductase, whose regenerates cellular glutathione, is decreased in the retina and plasma but elevated in the cardiac. Antioxidants such as -lipoic acid, quercetin, piperine, isoeugenol, coenzyme, Larginine, and nitroprusside had no influence on these benefits.

- **Catalase**

Peroxisomes contain catalase, which decomposes hydrogen peroxide into water and oxygen. Changes in enzymatic activity in diabetic mice that have been chemically induced. Catalase activity, for example, is continuously increased in the heart and aorta, as well as the brain, of diabetic rats. Catalase activity in the liver and kidney of diabetic mice is enhanced, despite reduced renal, hepatic, and red blood cell catalase activity. Psychotherapy with captopril, amino guanidine, melatonin, acetylsalicylic acid, DHEA, probucol, -lipoic acid, and stobadine, all of which were given before or at the same time as the diabetogen, corrected the changes in catalase activity caused by diabetes[7]. Treatment of established diabetes for four weeks or longer, on the other hand, somehow doesn't prevent or normalize diabetic consequences. Melatonin, quercetin, coenzyme, piperine, isoeugenol, gemfibrozil, and combination vitamin C, vitamin E, and carotene, for example, have no reversal effects.

- **Vitamins**

Vitamins A, C, and E are obtained from food and directly detoxify free radicals. They additionally participate in recycling processes, resulting in decreased vitamin forms. -Tocopherol is replenished when ascorbic acid recycles the tocopherol radical, and glutathione recycles the dehydroascorbic acid that is produced. Under some circumstances, these vitamins also promote toxicity by producing pro-oxidants. Vitamin E, which is part of the whole Peroxyl radical-trapping antioxidant system, shields membranes from lipid peroxidation by reacting directly with Peroxyl and superoxide radicals as well as singlet oxygen. Vitamin E insufficiency is associated with an increase in peroxides and aldehydes in various tissues. There have been contradictory findings on the amounts of vitamin E in diabetic animals and humans. Diabetes has been found to have no effect on vitamin E levels in the blood or tissues, as well as an increase or reduction in vitamin E levels. Discrepancies across studies. For example of the preventative or detrimental effects of vitamin E on diabetes-induced vascular aberrations may be due to the different types of blood vessels studied or the vitamin E dosage given.

- **Percentage of Nitrite**

Increasing data indicates that oxidative stress and alterations in nitric oxide production or activity are important factors in the development of diabetes problems. In the presence of biopterin,

NADPH, and oxygen, nitric oxide synthase converts arginine to citrulline. Nitric oxide, at normal levels, has a number of beneficial effects on the vascular system. Furthermore, late diabetes problems have been related to increased oxidative stress and consequent activation of the transcription factor NF-B. Nitric oxide production is increased by NF-B, which also is thought to be a mediator of islet beta-cell destruction. Nitric oxide may generate reactive Peroxyl nitrite radicals when it reacts with superoxide anion.

1.6.Pathophysiology Of Diabetes

Insulin stimulates the absorption of glucose and its utilization by muscle and fat cells. Insulin also inhibits glycogenolysis and gluconeogenesis in liver tissue, as well as lipolysis in adipose tissue. Some mechanisms are redirected in the other way if insulin isn't working correctly. When cells fail to eliminate glucose, extracellular glucose levels rise while glucose levels within the cells fall. Lipolysis rises, fatty acid and diabetic ketoacidosis increase, and protein or gamma globulin production decreases as a result. Hyperglycemic coma and osmotic diuresis may occur as a result of an elevation in extracellular glucose[8].

- **Diabetes Consequences**

Metabolic acute complications and systemic late complications, which have been divided into microvascular and macrovascular degenerative problems, are two types of diabetic complications. Hypoglycemia, hyperglycemia, hyperosmolar hyperglycemia, and diabetic ketoacidosis are among acute consequences. Eye difficulties, foot problems, heart attack and stroke, renal problems, nerve damage, gum disease and other oral problems, as well as associated diseases including cancer and sexual problems in men and women, are examples of systemic late consequences. Microvascular degeneration includes retinopathy, nephropathy, neuropathy, and foot issues, whereas macrovascular degeneration includes cardiovascular disease, stroke, and peripheral artery disease.

1.7.Hyperglycemia And Non-Enzymatic Glycosylated Proteins

By a process combining glucose oxidation, protein glycation, and oxidative degradation, diabetic hyperglycemia causes an increase in free radical production. The consolidation of glucose with the -amino group of lysine, the -amino group of an N terminal amino acid, or perhaps the amines of nucleic acids is known as glycation (non-enzymatic glycosylation). The very first reaction is the creation of an unstable Schiff base, which is reversible and achieves a steady state in hours. Rearranging the Schiff base into an Amadori product takes around 28 days to achieve a steady state and is also reversible[9]. Amadori products undergo numerous dehydration events and rearrangements to permanently produce AGEs when molecules have sluggish turnover rates. Several of the irreversible consequences of diabetes, such as enlarged extracellular matrix, cellular hypertrophy, hyperplasia, and vascular problems, are thought to be caused by AGEs. Fructosamine and glycated hemoglobin levels are two markers used to estimate the degree of protein glycation in diabetes. Glycation that occurs without the use of enzymes may affect the structure and function of antioxidants.

Only a few medicines, such as melatonin, probucol, vitamins C and E plus -carotene, and -lipoic acid, decrease high blood glucose levels in diabetes. Because most antioxidants do not cure diabetes-induced hyperglycemia, they must be used in conjunction with insulin treatment.

1.8.Peroxidation And Diabetes Mellitus-Related Parameters

Free radicals are extremely unstable chemical entities containing one or more unpaired electrons that have a particular characteristic. Free radicals are required for intracellular signaling as well as extracellular signal-regulated enzyme pathways that control gene expression. Radiation,

pollutants, RNS, ROS, smoking, neutrophils and macrophage formation, and industrial emissions are all sources of free radicals in cells and their environment.

Furthermore, free radicals have harmful consequences, and the body employs a variety of antioxidant mechanisms to protect itself from these harmful effects. The body suffers from oxidative stress when the equilibrium between the quantity of free radicals and the antioxidant capacity of the body is disturbed. Alongside cellular deterioration, oxidative stress eventually leads to cell death, and oxidative stress has been linked to the etiology of more than 50 disorders thus far.

2. LITERATURE REVIEW

E. Birben et al. studied the several researchers have associated oxidative stress to the pathogenesis of chronic problems. The generation of oxidant agents such as reactive oxygen and nitrogen species rises during hyperglycemia. Oxidative stress is caused by this process, which is accompanied by a reduction in the activity of antioxidant enzymes. This redox imbalance damages essential biomolecules such as proteins, lipids, and DNA, and leads the body to produce toxic compounds. Several pathways, including flux through into the polyol pathway, intracellular production of advanced glycation end merchandise precursors, protein kinase-C activation, and increased activities of the hexamine pathway, are implicated in the creation of conditions of oxidative stress and, as a result, diabetes complications. The research of polymorphism in the genes of antioxidant enzymes, from the other hand, shows that certain gene polymorphisms decrease the antioxidant activity of the enzymes. This article will cover a number of research to show how oxidative stress plays a part in the development of diabetes and how antioxidants may help diabetic complications [9].

Abraham Nyska studied the Oxidative and other radicals have a role in a wide range of biological processes, including mutation, cancer, degenerative and other illnesses, as well as ambition, aging, and development. ROS are widely known for their dual roles as both harmful and helpful organisms. The goals of this overview are to characterize oxidative stress phenomena, terminology, definitions, and basic chemical characteristics of the species involved; examine biological benchmarks susceptible to oxidation and also the organism's coping strategies against all of these reactive metabolites; and scrutinize methodologies, which would include immunohistochemically markers, used during toxicological pathology in the species involved. Because ROS and other free radicals are close to the end and strongly reactive in a generic way, direct detection is challenging. As either a result, secondary products such as amino acid derivatives, nucleic acids, and lipid peroxidation are often measured to assess ongoing oxidative damage. The overall reducing power of biological fluids and tissues has been evaluated using electrochemical techniques based on voltammetry measurements. This method may be used to evaluate a biological site's phytonutrients ability and track changes in pathological conditions. As a result, this review covers a variety of subjects that are important to comprehending oxidative stress phenomena, as well as tools for those who want to study and research in this area[10].

Awanish Kumar studied the production of reactive species as well as free radicals, which cause oxidative and nitrosamine stress, is intimately related to the multitude of problems associated with diabetes. Increased oxidative stress is a universal cause and consequence of diabetes, and it's believed to be at the root of the cellular alterations that produce diabetic problems. The whole relationship between the variables chain creates a vicious cycle that lies underneath several layers of possible medicines in its study. In this respect, this review summarizes the research on the link between type 2 diabetes and increased lipid peroxidation, as well as the efficacy of different antioxidants that are or may be utilized to reduce oxidative stress. A single antioxidant treatment strategy cannot be the solution since the difficulties are like a woven matrix of many

degrading processes. As a result, novel fixed-dose combinations of efficient antioxidants that target major reactive oxygen generating sources, imitate endogenous antioxidants, and scavenge reactive species produced are needed to balance the pro and antioxidant cycle. This study focuses on preclinical and clinical trial results with therapeutic antioxidants in type 2 diabetes, as well as a short discussion of antioxidant-based treatment successes and mistakes[11].

3. DISCUSSION

In particular, oxidative stress is implicated in the development and progression of diabetic problems. Furthermore, the findings of many studies indicate that antioxidants, particularly those containing numerous antioxidant biomolecules, such as vegetables, fruits, and seeds, are helpful in avoiding diabetic complications. However, extensive clinical studies have demonstrated that a high amount of one kind of antioxidant may be detrimental, since antioxidants eliminate free radicals by giving them electrons, and in the exclusion of other appropriate antioxidants, it can convert into a pro-oxidant. Because several antioxidants in fruits and vegetables form an antioxidant chain, it is suggested that vegetables, fruits, and herbs having numerous molecules of antioxidants be utilized instead of taking a single antioxidant in large doses for the treatment of illnesses like diabetes. To summarize, large-scale cohort studies, as well as systemic and meta-analysis investigations, are required to determine whether antioxidant substances and circumstances have a beneficial effect on diabetes recovery.

CONCLUSION

Evidence on the influence of oxidative stress in diabetic complications are covered in this article. The findings indicate that glucose metabolism and FFA enhance oxidant products like ROS and RNS via various routes, resulting in oxidation of key bio-macromolecules like lipids, nucleic acids, and proteins, along with nephropathy, neuropathy, and cardiovascular disease. Diabetes in rats caused by STZ or alloxan is a well-known animal model of type 1 insulin-dependent diabetes mellitus. Increased oxygen free radical generation has been related to glucose oxidation and non-enzymatic protein oxidative stress, both of which contribute to the development of diabetes and its complications. Exogenously given antioxidants' therapeutic benefits in animal models have already been widely investigated in recent years, giving some understanding into the connection between free radicals, diabetes, as well as its consequences. In vitro and clinical investigations may offer new helpful methods to investigate the correlations between oxidant stress as well as diabetes, and more research into the pathways through which increased oxidative stress accelerated the development of diabetic complications is essential.

A REVIEW ON NATURAL SURFACTANTS

Mr Krishnaraj Singh*

*SBAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: hodbio-tech@sanskriti.edu.in

ABSTRACT

Natural surfactants, also known as bio surfactants, are exogenous amphiphilic biological chemicals generated by a range of microorganisms from a number of sources, including waste products. Because of their unique characteristics, including such low toxicity, functioning under severe circumstances, based on renewable chemicals, and biologically degradable nature, there's always growing interest in this subject. Since of relatively low toxicity, biodegradability, and relative stability in a variety of physicochemical conditions, they are referred to as "ecofriendly." Despite having a wider range of structures and superior physicochemical characteristics than chemical solvents, bio surfactants cannot compete with comparable synthetic counterparts due to high upstream and downstream costs. Low productivity, costly downstream processing, as well as a lack of adequate knowledge of the bioreactor technologies for their synthesis limit the commercialization of these environmentally beneficial biomolecules. However, we anticipate that in the future, improved reactor design and material recycling technologies will be developed, as well as the screening of overproducer microbial strains. The current study focuses on bio surfactants in general, including their characteristics, benefits and drawbacks, manufacturing, characterization, and use, as well as recommendations for future research.

KEYWORDS:*Applied Aspects, Bio Surfactants, Biodegradability, Future Trends, Productions.*

1. INTRODUCTION

Surface Active Agencies, or SURFACTANTS, are amphipathic compounds with the capacity to form micelles. Surfactants are effective emulsifiers, dispersing, and foaming agents because of their surface activating capacity. They aid polar chemicals' immersion in organic solvents. Surfactants are also the active components in soaps and detergents, and they're frequently employed to remove oily materials from a given medium[1].

So far, the focus has been on developing an alternative environmentally benign method for producing various types of organic or bio surfactants. Surfactants produced by living cells are known as bio surfactants. They have the unique ability to decrease surface and interfacial tension via the same processes as synthetic surfactants. The main activities of bio surfactants include

emulsification, dispersion, dissolution rate, foaming, wetting, detergent capacity, and antibacterial activity in certain instances[2]. Exolipase makes up the vast majority of bio surfactants, but some are cell-bound. Bio surfactants are biologically generated from different substrates such as oils, sugars, alkanes, and wastes by yeast, bacteria, or fungus. Sophorolipids were the very first microbial surfactants to hit the market. Because of their benign and biodegradable nature, bio surfactants are regarded ecologically beneficial. Bio surfactants have sparked a surge of interest owing to their eco-friendliness, variety, large-scale manufacturing potential, selectivity, performance under extreme conditions, and potential uses in environmental fortification. Bio surfactants have attracted the attention of the industry and academia in recent years[3].

1.1.Bio surfactant Characteristics

Surfactants have had both hydrophilic and lipophilic moieties, making them amphiphilic. Surfactants with this property may reduce surface and interfacial tension and produce emulsions. Because of their environmentally benign nature and reduced toxicity as compared to synthetic surfactants, enthusiasm in bio surfactant research and use is steadily growing. Emulsification, foaming, wetting, cleaning, surface activity, phase separation, and crude oil viscosity reduction are just a few of the many functional characteristics that make among the most versatile process chemicals. It until critical nanocrystals concentration is reached, the actions of bio surfactants are dependent on their concentration. Micelles, bilayers, and vesicles are formed by the association of bio surfactant monomer molecules above the CMC (Fig. 1). Bio surfactants have this characteristic, which allows them to reduce surface and contact resistance while also increasing the absorption and bioavailability of nonpolar organic molecules. Surfactant efficiency is typically measured using the CMC. The CMC of more effective bio surfactants is lower, implying that less bio surfactant is required to reduce surface tension[4].

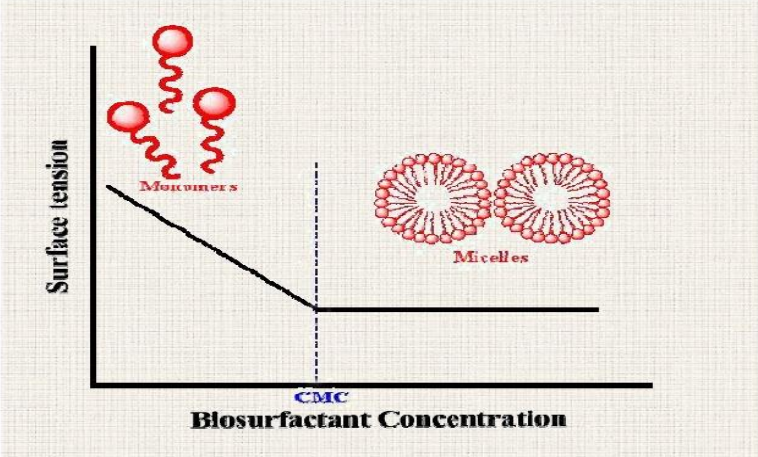

Figure 1: Relationship between surface tension and bio surfactant concentration & formation of Micelles

The following are recommended characteristics of bio surfactants:

- **Emulsification and De-emulsification:**

Emulsification is the dispersion of one liquid into another as tiny droplets, causing two or more substances to mix. Deemulsification is the process of breaking emulsions by disrupting the stable interface between the bulk and interior phases. This is crucial in the oil production process. Bio surfactants may be used to create stable emulsions with months or years of shelf life. The capacity of bio surfactants to maintain or destabilize the emulsion. Bio surfactants with a large molecular mass are often superior emulsifiers. T. bombicolasophorolipids have been

demonstrated to decrease surface and interfacial tension, although they are poor emulsifiers. Although liposomes do not decrease surface tension, they may emulsify edible oils. Bio surfactants have this characteristic, which is very helpful in the cosmetics and food industries[5].

- **Biodegradability:**

Bio surfactants seem to be much more biodegradable then their synthesized equivalents owing to their biological nature. Biodegradability tests of sophorolipids produced by the non-pathogenic yeast Candida bombicola, conducted in accordance with the OECD Guidelines for Chemical Testing, revealed that bio surfactants begin degrading immediately within a week of cultivation, whereas synthetic surfactants do not degrade after seven weeks. Another study found that rhamnolipids bio surfactants are biodegradable in both aerobic and anaerobic environments, while synthetic surfactant Triton X-100 is only partly biodegradable in aerobic and anaerobic environments.

1.2.Benefits

The majority of chemically produced surfactants are petroleum-based. As a result, they are often non-biodegradable and therefore hazardous to the environment. Synthetic surfactants, like other chemicals, may bio accumulate, and their manufacturing methods and therefore by can be harmful to the environment. Because there is a growing awareness of the need to preserve this environment, natural-source surfactants may be used instead of chemically produced ones. Despite their water solubility, they may have CMCs that are much lower than synthetic surfactants with comparable structures[6]. Nonionic, multicomponent mono rhamnolipids mixtures, for example, where the heptyl chain network that enables is the most common, with CMC values ranging from 1Mm to 10mM, depending on the ion concentration. The CMC value rises when the pH rises, and the rhamnolipids get deprotonated. Research has indicated that bio surfactants have many benefits over their co - products.

- **Biodegradability:**

These surface active substances do not stay in the atmosphere and are quickly destroyed by microorganisms due to their low toxicity, organic origin, and simple chemical structure.

- **Digestibility and biocompatibility**

They have an inherent compatibility due to their biological sources, which allows for unrestricted use in cosmetics, medicines, agricultural sectors, and as useful food additives.

- **Activities on the Surface and at the Interface:**

Mulligan claims that a good surfactant may reduce water's surface tension between 72 to 35 mN/m and the interfacial tension between water and cyclohexane from 40 to 1 mN/m. Surfactinsmay reduce the surface tension of water to 25mN/m and the water/hexadecane surface tension to 1mN/M.

- **Raw Material Availability:**

Bio surfactants may be made from a variety of relatively inexpensive basic ingredients. Carbon sources like as hydrocarbons, carbohydrates, and lipids may be utilized alone or in combination.

- **Production Economics That Are Acceptable:**

Hazardous wastewater and by-products may also be used to make bio surfactants, which is advantageous for large-scale manufacturing.

- **Specificity:**

Because bio surfactants are complex chemical compounds with particular functional groups, their actions are typically quite specialized. This characteristic is crucial in the detoxification of particular contaminants, the creation of specialized cosmetics, the de-emulsification of economic emulsions, as well as many medicinal and food applications.

- **Environmental Management:**

Bio surfactants are useful for oil spill cleanup, industrial emulsion handling, industrial effluent detoxification and biodegradation, but instead contaminated soil biosorption.

1.3.Disadvantages

Despite their many benefits, bio surfactants can have the following drawbacks.

- **Toxicity:**

Although bio surfactants are believed to be ecologically benign, certain studies have shown that they may cause toxicity in the environment under specific conditions. The impact is lesser when compared to synthetic surfactants. Again, bio surfactants have no negative effects on the kidneys, heart, lungs, or liver, and they do not interfere with normal blood clotting time. So, with cautious and regulated application, these intriguing surfactants will undoubtedly aid in the improved cleaning of harmful environmental contaminants and offer us with a healthy living environment.

- **Expensive Large-Scale Manufacturing:**

Large-scale production of natural surfactants may be costly. However, this issue may be solved by using waste substrates while also fighting their polluting impacts, thus balancing the total expenses.

- **Finding Pure Substances Is Difficult:**

Pure substances are difficult to come by, which is especially important in food, cosmetics, and pharmaceutical applications. It may be caused by the many processes needed in separation process of diluted broths.

1.4.Characterization of Bio surfactants

Surfactants that are chemically produced are typically categorized based on the type of their polar groups. Bio surfactants are classified primarily according to their chemical structure and microbiological origin. They are amphiphilic in structure, with a hydrophilic and a hydrophobic moiety. The rate of solubility of bio surfactants in water is determined by their hydrophilic component. Capillary action is controlled by the lipophilic portion. Ester linkage (particularly lactones) with organic and inorganic acids, amide linkage (single and peptide), or glyosidic linkage connect these two components[7].

- Surface active molecules with low molecular weight: capable of effectively lowering surface and interfacial tension. Glycolipids, lipopeptides, and phospholipids are three of the most common types.
- Surface active compounds with a high molecular weight are excellent emulsion stabilizers. Polymeric and particulate surfactants are two of the most common types.

1.5.Manufacturing of bio surfactants

During their development, many microorganisms, including bacteria, yeasts, and fungus, may generate surface-active compounds[8]. As an example, Rhanolipids from Pseudomonas aeruginosa and Surfactin from Bacillus Subtilis are two bacteria that produce bio surfactants.

1.5.1. Bio surfactant-producing yeasts: Torulopsisbombicolasophorolipids and Candida petro hilum peptididolipid.

1.5.2. Bio surfactants produced by fungi: Sophorolipids from Candida batiste and Candida bombicola

- Oil Residues: Oil wastes from vegetable oil refineries and indeed the food sector are utilized as suitable substrates for the manufacture of bio surfactants. Sunflower seed oil and oleic acid may be utilized by Thermos thermophiles HB8 to produce rhamnolipids. Incorporating these less expensive oils and oil wastes as a feedstock in industrial production medium may lower total bio surfactant manufacturing costs.
- Dairy Protein powder: One kilogram of paneer yields about 6 liters of whey. Whey from the dairy industry may also be used as a cheap and long-lasting substrate for bio surfactant fermentation. Via dairy waste as a substrate, the yeast Cryptococcus curates was able to produce large quantities of sophorolipids using a two-stage growth method.
- Starchy Refuse: Starchy waste materials are also low-cost raw materials that may be used to make bio surfactants. The potato processing business generates a significant amount of starchy trash. Carbon, nitrogen and sulfur, inorganic minerals, trace elements, and vitamins are all abundant in these wastes. Thompson reported on the use of potato effluents as substrates for surfactant synthesis.
- Molasses: Molasses is a co-product of the sugar industry that is produced during the production of sugar from sugar beet or sugarcane and is a significant source of accessible carbon. For the synthesis of rhamnolipids bio surfactant utilizing P. aeruginosa, Patel and Desai used molasses and corn-steep liquor as the main carbon and nitrogen sources.

1.6. Factors Affecting Bio surfactant Production

Bio surfactant synthesis is influenced by both the producer strain and the culture conditions[9]. As a result, a number of factors influence not just the quantity of bio surfactant used, but also the kind of product that is generated.

- **External Factors:**

Having a significant amount of bio surfactants necessitates optimizing the bioprocess, since variations in pH, temperature, aeration, and agitation speed may all affect the result.

- **pH:**

Zinjarde and Pant investigated the impact of pH on bio surfactant synthesis. They found that the product performed best at a pH of 8.0, which is really the typical pH of sea water.

- **Climate:**

Various microbial activities for the generation of bio surfactant are temperature sensitive and are influenced by small changes in temperature. The majority of bio surfactant manufacturing reported so far have been done at temperatures between 25 and 30 degrees Celsius.

- **Aeration and Agitation:**

Simultaneous aeration and agitation help oxygen transport from the gas phase to the aqueous phase. As a result, these are important variables that affect bio surfactant synthesis.

- **Carbon Sources:**

Organic substances play an important role in microorganism development as well as the generation of bio surfactants. Water-soluble carbon sources include glycerol, glucose, mannitol, sodium acetate, and ethanol, while water-immiscible carbon sources include n-alkanes and olive oil.

- **Nitrogen Sources:**

N is required for microbial development since it is required for protein and enzyme synthesis. As a result, nitrogen is critical in the bio surfactant manufacturing process. Several nitrogen molecules have been utilized to make bio surfactants, including yeast extract, ammonium nitrate, ammonium sulphate, urea peptone, sodium nitrate, meat, and malt extracts. The most common nitrogen source for bio surfactant synthesis has been discovered to be yeast extract.

Natural detergents are becoming more popular as environmental concerns about surfactants grow. Krister Holmberg's research, which focused on work published since 1998, looked at three types of natural surfactants: amphiphilic generated by yeast or bacteria, amphiphilic with a natural polar head group, and amphiphilic with a natural hydrophobic tail. Surfactants of both high and low molecular weight are produced by microorganisms. The study focused on molecules of low molecular weight. Sugars and amino acids are two of the most prominent natural-source surfactant polar water molecules. Alcohol surfactants are a hot topic of study, and the review includes three different types: alkyl glucosides, alkylglucamides, and sugar esters. Triglyceride monoethanolamides and sterol ethylates are two kinds of natural hydrophobic tails used as surfactants. Surfactants produced via organic synthesis are addressed in terms of their production routes as well as their physico-chemical characteristics[10].

2. DISCUSSION

The commercial application of bio surfactant on a wide scale is restricted due to their complexity and high manufacturing costs. Rhamnolipids and surfactin have been commercially accessible till now. Even at these businesses, however, easily accessible goods are not always for sale. One of the reasons for this may be because rhamnolipids are the only bio surfactant authorized for use in medicines, cosmetics, and food items by the US Environmental Protection Agency. Surfactants generated by bacteria and yeast, surfactants based on either sugar or amino acid as

polar head group, and surfactants based on either fatty acid or sterol as hydrophobic tail have all been reviewed in recent years. All three categories are significant and have a lot of study going on in them. Natural surfactants produced via these methods are usually well described, and their performance is comparable to that of conventional surfactants.

3. CONCLUSION

Despite many laboratory successes in bio surfactant synthesis, industrial scale production remains a challenge. Any product's commercial manufacturing is determined by market demand, raw material availability, and production cost. The generation of bio surfactant is hampered by low productivity, high downstream processing costs, and a lack of adequate knowledge of bioreactor systems. We anticipate that super-active microbial strains will be created in the future utilizing genetic manipulation for industrial production. In the future, new techniques will be developed, as will the finding of more trustworthy sources. As a result, yields would be higher, manufacturing costs would be lower, and novel bio surfactants would be found, with the chemistry of these molecules better understood. As a result, bio surfactants will soon be able to compete effectively with their synthetic counterparts in the surfactant business

EVIDENCE FROM INDIA: IMPACT OF MOBILE PHONE TECHNOLOGY ON THE PERFORMANCE OF AGRICULTURAL EXTENSION SERVICES

Mr. Swapnil Raj*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: swapnil.cse@sanskriti.edu.in

ABSTRACT

The effect of mobile phone increased involvement in agricultural extension delivering services in India is investigated in this research. The quantity, quality, and speed of delivering services have all increased substantially as a result of the intervention, according to the statistics. There are additional advantages in terms of increased knowledge and awareness of new agricultural techniques, farmers' desire to experiment with new technologies in the future, and financing availability. Farmers from low-income and low-education backgrounds are not discriminated against in the system. As a result, a well-utilized technology system aided by trained village youngsters may be used to promote inclusive development. The fundamental source of development is vertical innovations produced by a developing research industry, according to an endogenous growth model. The quantity of research in each period is decided by the anticipated amount of research in the following period, according to a forward-looking difference equation. Creative destruction is one cause of this intertemporal connection. In other words, the possibility of greater future research deters current research through threatening to suffocate the rents generated by current research.

INTRODUCTION

Small - scale farmers, who predominate the developing world's terrain, need sufficient access to education, information, and other services in order to enhance their agricultural practices. It is critical to provide farmers with the necessary information and services in some kind of a timely and effective manner. Due to the absence of infrastructure, farmers in rural communities are excluded. Agricultural extension services are an essential instrument for transferring information, providing guidance and education to farmers concerning new techniques and equipment, and encouraging positive agricultural advances. Due to a lack of information, expertise, inputs, and management, farmers often adopt sub-optimal agricultural methods. The preponderance of resource-poor farmers in India have limited access to public services; almost 60% are excluded[1]. Enhanced version staff must collect and provide a wide variety of

information to small farmers in a timely manner. Farmers have a pressing need for market data, land records, farm management data, and pest and disease control information, as well as pesticide usage and management. Digital revolution (ICT) may play a significant role in this respect. In agriculture, however, ICT is not completely used. Farmers who are poor and disadvantaged, women, and rural regions are all excluded. Farmers need suitable ICTs to utilize and enhance their knowledge of agricultural techniques[2].

Cole and Fernando (2012) assess the effect of agricultural counseling services (referred to as AO) that consist of a weekly automated voice message delivered to chosen farmers. Their study, on the other hand, concentrates on cash crop farmers who must have access to a cell phone. These two criteria ruled out the most vulnerable farmers. Furthermore, the fact that they used a randomized design within the same village increases the risk of spillovers from the treatment to the control group. This project sent a uniform push notification to all programed mobile phone users. Although voice messages provide information, they do not allow receivers to express their urgent requirements. As a result, the service's efficacy will vary from that of those that provide responsive capacity building[3].

The benefits from SMS messages regarding market and environment information sent to farmers' mobile phones are estimated by Fafchamps and Minten (2012). They discovered that treatment had an impact on crop grading and spatial arbitrage, although the size of the effect was modest. Farmers who benefited from this service, like those who benefited from the AO initiative, possessed cell phones without the ability to record videos. Farmers sometimes find it difficult to explain difficulties in their own language, therefore video pictures might be helpful in properly presenting the issues to advisors. Farmers are solely recipients of push notifications sent to their cell phones[4].

1.1.Background

Agriculture extension programs in India have undergone significant modifications. The demand for extension services far outnumbers the available supply. Civil service and public spending reform, training and capacity development, public-private partnerships, and ICT use are among the supply-side initiatives. The governmental sector's Diversified Agricultural Support Project and National Agricultural Technology Project, as well as the private sector's e-Choupal project, are examples of initiatives. In rural regions, E-Choupal includes the installation of PCs with Internet connection[5]. Many limitations face public sector programs, including inadequate communication, insufficient ability, and a lack of sufficient funding. Without rapid technology, smallholder participation in distant places is severely limited. In 2008, mobile phones were not common in rural India, particularly in impoverished areas like Madhya Pradesh, and no one owned a smartphone. A few projects have utilized ICT to improve agricultural extension services, but the poorest farmers are still out of reach.

1.2.The KHETI Initiative

The KHETI method consists of village helpers known as Munnas who utilize cellphones to produce Short Dialogue Strips to help small/marginal farmers communicate with agricultural specialists. SDSs are audio-visual productions on agricultural problems and expertise in the local area. This revolutionary mobile phone-based information system, which is driven by demand, allows users to send and receive multi-media communications. Farmers wanted prompt and high-quality services, but the availability of such services was hampered by the physical distance between farmers and agricultural specialists. Similar issues were discovered in other investigations[6]. The KHETI was launched by the Sironj Crop Producers Company Private Limited, a cooperative-type NGO. SCPCL was founded in the Sironj Block of Madhya Pradesh's Vidisha district in Central India. Members of the SCPCL have restricted access to assets. The infrastructure in villages is inadequate. Wheat, gram, and maize are the major winter crops,

while soybean is grown during the rainy season. Prior to the invention, SCPCL offered information and services to its members in the same way as KHETI did, but it had trouble reaching all of them in a timely manner.

The KHETI system is shown in Figure 1. In comparison to the AO project, KHETI is more creative since farmers may show specialists footage of their issue, such as a pest assault, and get better answers. Munnas serve as mobile phone carriers and assist customers with video production. In three stages, KHETI is anticipated to have an effect on results. First, agricultural extension services would be more widely used, faster, and of higher quality. Second, increasing the quantity, quality, and speed with which agricultural services are provided will enhance farmers' knowledge and skills[7]. Third, agricultural production, income, and welfare are anticipated to be influenced by knowledge and skills. There are many important variables at play in each stage. Farmers are likely to utilize the services to bring about desired improvements if the services are of sufficient quality, but this may be influenced by key variables.

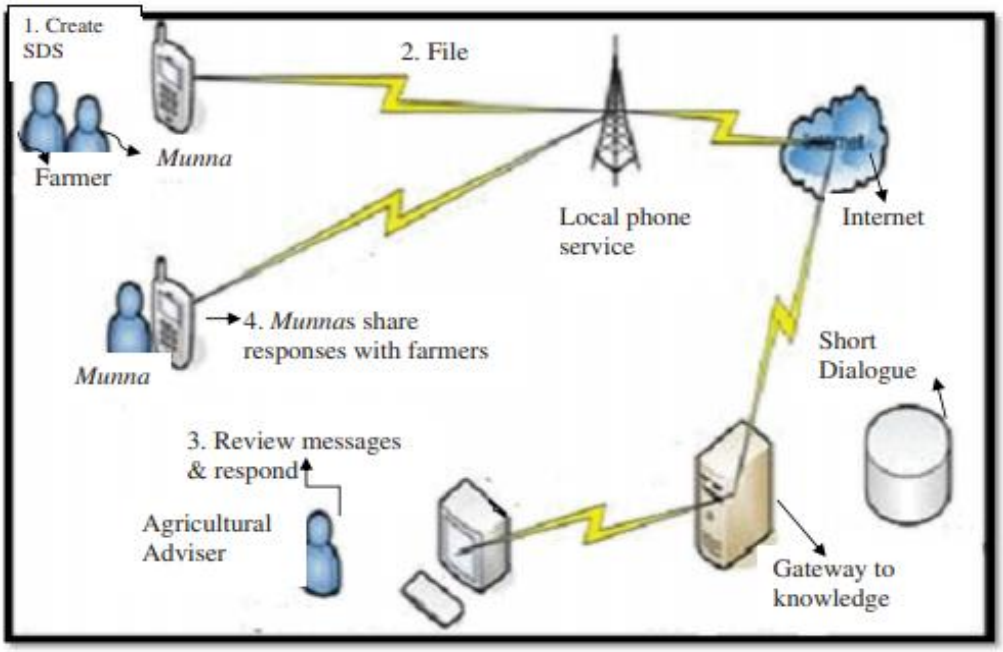

Figure 1: Using Short Dialogue Strips to seek advice from agricultural adviser.

Producers are believed to have the ability to absorb knowledge since KHETI is demand-driven. The causal chain should work if the restrictions to utilizing the services are eliminated; farmers would utilize the services to bring about the desired improvements.

1.3.Indicators of Impact

The following is how we assess impact:

Where I stands for ‘impact,' O for the magnitude of the interpretable impact indicator, T and C for treatment and control groups, I for sample units, and n for sample size. As a result, the impact is defined as the change in outcome as a result of an action.

We look at indicators including changes in the amount and quality of extension services used, as well as the usefulness, speed, and increase in agricultural knowledge. We also looked at how KHETI has affected farmers' attitudes and aspirations. We concentrate on those other under-researched aspects of rural development for the following reasons. Employment has been

employed as a common metric of effect, but we focus on all other inadequately dimensions of poverty alleviation for the reasons stated[8].

For starters, many aspects of rural development may be measured not just in terms of increased "farm productivity/income," but also in terms of increased farmer skills. In today's world, enhanced knowledge and skills have a far wider relevance and applicability (Sen, 1989). We have highlighted increased capacities via the extra quality and quantity of information that farmers acquire through KHETI since knowledge is an important prerequisite for any type of future effect. Also, being acquainted with a modern technology indicates that you are aware of a larger range of options. Experimenting with or watching any new technology necessitates some level of active participation, which is a legitimate engagement in and of itself. Farmers would select the best option from their choice bundle after learning about new techniques.

1.4.Resultant Effects on Beneficiaries & Delivery

The following is how access and knowledge were conceived. Farmers were asked to evaluate their primary limitations, as well as whether and to what degree these constraints had been alleviated since the introduction of mobile-enabled Munna services.

- The four major restrictions have the following characteristics:
- A basic understanding of agriculture,
- New manufacturing methods and technologies
- Basic agricultural activity funding, and
- Financial support for the use of certain agricultural knowledge or practices

The inverse of these characteristics' scores is used to create an awareness-knowledge index. Farmers were permitted to respond to the relevant questions based on their own perceptions. Because they are from the same sub-district, we presume they have comparable cognitive abilities.

1.5.Effect on Farmers' Expectations

The experience of utilizing mobile phone technology to help agricultural extension services may have opened people's eyes to contemporary technology and external developments, as well as their significance to farming and life in general. We asked the farmers whether they believe their experience with KHETI would lead them to try more new agricultural technology in the future, and if they think their experience with KHETI will lead them to try more new technology and new ways of living in the future.

1.6.Effects of Heterogeneous Treatment

While the significance of technology advancement to development is undeniable, there is increasing worry about the potential of a "digital gap," in which the poorest and least educated are unable to fully benefit from new technologies' promise. We put this theory to the test by comparing AO use and knowledge acquisition across educational levels. We concentrate on respondent education for at least two reasons: first, although the service is intended to be accessible to illiterate users, a literate audience that can take advantage of instructional content may find it simpler to use or navigate. Second, educated people may have a greater ability to learn.

Years of education, pesticide use, even sowing decisions given the variations in the usage of and reported dependence on AO based on education, it's reasonable to ask whether we're seeing similar variances in how agricultural methods react to AO. We examine the impact of AO and education on pesticide usage and planting choices in tables not published. There are no effects

that are heterogeneous. Importantly, the most immediate and significant finding in our research is that imidacloprid adoption among AO users does not seem to change consistently with years of higher education[9].

1.7.Using information and communication technologies (ICTs) in agricultural extension

For decades, "traditional" ICTs have been utilized to provide advisory services. In developing nations, weather related agricultural information are routinely broadcast on radio and television, and rural tele centers have given information on pricing and quality. National agricultural ministries in several countries have tried to incorporate ICTs into knowledge delivery services by creating district information centers. Many of these efforts have shifted away from "traditional" ICTs and toward mobile telephony, which includes voice, SMS, and internet-based services, as mobile phone coverage has grown:

- Telephone-based knowledge delivery services that offer advice on agricultural techniques and market access are the most common kind of voice-based information delivery service. For agricultural extension assistance, several of these agencies utilize call centers or hotlines. The mechanisms vary from basic telephones (landlines or cell phones) to more complex technologies and computer applications.
- Regular radio broadcasts that offer market pricing and perhaps other agricultural information, along with dial-up radio that features a succession of brief segment audio programs, are examples of radio dial-up and broadcasts. A regularly updated repertoire of prerecorded agricultural material is often broadcast on the radio system. Farmers may ask the questions through SMS in certain instances, and the answers are broadcast over the radio in others.
- SMS-based extension services gather and distribute information primarily via message-based platforms. This covers data collecting through a simple SMS-based questionnaire, requesting information by SMS and getting a response via SMS, and receiving bulk SMS on agricultural subjects.
- Tele centers and internet kiosks are common features of e-learning programs, allowing farmers to access internet technology for agriculture-related knowledge[10].

Market pricing, weather, technical assistance, and local market providers and purchasers are among the types of information supplied through these various methods. The bulk of these services concentrate on market pricing, weather, and transportation costs, owing to the fact that this data is simple to gather and distribute, objective, and less prone to estimation errors. Projects that offer information on agricultural methods and inputs are uncommon, maybe because such data is more complex and harder to communicate.

DISCUSSION

The needy farmers benefited more from the intervention than the better-off farmers, according to this study's findings. There is a common misunderstanding that contemporary technologies help just the wealthy, but that they do not aid those at the bottom of the economic pyramid. According to the findings of the study, mobile phone technology may have a major developmental impact on the poor. This project's success may be attributed, in part, to the use of a suitable technology, Munna's mobile phone technology, rather than a more sophisticated networked Internet system in India's poorest regions. This is a valuable lesson for future technology for development initiatives that we can take from the KHETI experience. Our data also indicates that the mobile phone's integration of audio and video technologies, as well as the mediation of trained village youth, Munna, allowed farmers with low levels of education or land to benefit from this mobile phone-assisted extension service. If the services are more closely linked to agricultural methods and technology, and of higher quality, the effect is greater. Future research could focus on

identifying improvements in various farm practices, efficiency, and competitiveness as a result of enhanced extension services provided by mobile phone technology, and then directing innovation toward supporting efficient and competitive farm practices by small and marginalized farmers. The technology was implemented with the help of a research funding organization, however it cannot be maintained in its present state.

CONCLUSION

The effect of new, video-enabled mobile phone technology on the speed and quality of agricultural service delivery is investigated in this research. Small and marginal farmers who used the services increased their awareness and agricultural expertise, as well as their access to finance. This assessment is based on the KHETI action research project, which facilitates the rapid transmission of audiovisual conversations between farmers and agricultural specialists. Munnas, or local teenagers, use cellphone technology to link farmers with agricultural specialists. Its goal is to provide timely and suitable assistance to all chosen farmers in order to address their issues. We use data from structured questionnaires to gather pre- and post-intervention survey data. Farmers thought the services were of higher quality than before the intervention. Farmers have become more comfortable with new technologies and adjusting to new things for the future as a result of their use of the services. KHETI, on the other hand, may be modified by the government to enhance the effectiveness of its extension services delivery, given the present rise of cheaper cellphones and the cost-effective employability of Munnas. Munnas may be hired by the state government to save money by employing fewer specialized specialists for successful extension services. Partners may assist in the development of longer-term extension service effect indicators, allowing for the evaluation of sustainability and ongoing adoption of ICT-based interventions like the KHETI. Because current evidence of knowledge-aspirations-productivity links is still sparse, our findings suggest that intervention-based research investigating such connections be given more attention.

REVIEW OF MICROALGAE-BASED BIOFUEL OIL AND GAS MANUFACTURING METHODS

Dr Durgesh Wadhwa*

*SBAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: hodchem@sanskriti.edu.in

ABSTRACT

Many individuals mistakenly think that the material is exclusively used for transportation. Biofuel, on either hand, may generate hydrogen, clean oil, and even be used as a cooking oil. Biofuels may be used to replace a variety of energy sources, including vehicle fuel and central domestic heating. There have been two major concerns recently: the environment as well as the energy crisis. Global warming is a problem for the environment. Microalgae, as biomass, may be turned into energy such as biofuel oil and gas, making them a viable renewable energy source. This article provides a quick overview of the major microalgae energy conversion mechanisms. Due to the high-water content of microalgae, not all biomass energy conversion methods may be used. Oil or gas may be generated using thermochemical processes, while ethanol and biodiesel can be produced utilizing biochemical methods. Because the characteristics of the microalgae product are almost identical to those of fish as well as vegetable oils, it may be used as a fossil oil replacement.

KEYWORDS:*Bio Fuel, Oil Production, Micro Algae, Thermo Chemical, Biochemical.*

1. INTRODUCTION

Everyone understands that burning fossil fuels has contributed to global warming; therefore, renewable clean energy is needed to replace fossil fuels with biomass in order to decrease CO_2 emissions. Another problem is the energy crisis, which has an effect on domestic energy circumstances as well as local social life as global petroleum crude oil prices rise. As a result, in order to address the critical problem raised above, renewable energy should be created. Atmospheric concentrations of greenhouse effect greenhouse gases in the atmosphere have caused global warming, which has become a major environmental issue. Three fundamentally distinct approaches may be used to reduce the buildup of atmospheric CO_2, the main driving factor behind predicted global warming[1].

1.1.The Usage Of Fossil Fuels Is Being Reduced:

CO_2 removal from the atmosphere. CO_2 produced by fossil fuel burning is captured and sequestered or used before it reaches the atmosphere. Biomass energy would contribute to a

reliable energy supply as well as to local community by increasing economic activity. Biomass may be obtained via the cultivation of specialized energy crops, the collection of forestry and other plant leftovers, and the use of biomass waste. By thermochemical liquefaction, even trash from homes and food businesses may be utilized as a raw material for oil production. Microalgae, for example, have a greater photosynthetic efficiency than other biomasses like trees. Microalgae may be utilized as a fuel substitute of fossil fuel if fuel can be extracted effectively from them. Biomass is a very attractive resource since the generation of fuel from photosynthetic organisms is a renewable process that uses sun energy. Biological CO_2 fixation and energy generation are anticipated to be viable options for reducing atmospheric CO_2 levels and averting future energy crises. Microalgae have long been recognized to use CO_2 gas as a source of carbon for growth. The reduce the amount of carbon dioxide levels in the atmosphere is a significant challenge, and various physical and chemical solutions have been suggested. Microalgae may generate micro algal oil via biological conversion to lipids or hydrocarbons or thermochemical liquefaction of algal cells, in addition to their capacity to fix CO_2. Lipids and fatty acids are found in microalgae as membrane components, storage products, metabolites, and energy sources. This article will cover a variety of techniques for converting microalgae to liquid fuel and gas, including biochemical and thermochemical approaches. Energy conversion through biochemical processes yields ethanol and biodiesel, while energy conversion via thermochemical processes yields oil and gas. The usage of microalgae oil products is also discussed in this article[2][3], [4].

1.2.Biomass To Energy Conversion

The following are some of the benefits of using microalgae as a biomass source: Algae are thought to be one of the most effective biological systems for collecting solar energy and producing chemical molecules. Algae are non-vascular plants that lack sophisticated reproductive organs (in most cases). Many algal species may be induced to generate large levels of certain, economically useful substances including proteins, carbohydrates, lipids, and pigments. Algae are microorganisms that divide their cells in a basic cycle. Microalgae may be cultivated in either seawater or brackish water. Algal biomass production systems are readily adaptable to different degrees of operational and technical expertise[5].

Microalgae, in fact, have the greatest oil output of any plant oil. It may yield up to 100,000 liters of oil per hectare per year, compared to 5950, 2689, 1413, or 952 liters per hectare for palm, coconut, castor, as well as sunflower, respectively. The Aquatic Species Program (ASP) looked at three major fuel generation possibilities. Methane gas, ethanol, and biodiesel are the three. Direct burning of algal biomass for the generation of steam or power is a fourth possibility, although the ASP did not give it considerable consideration. Many algae have a high oil content. According to Oilgae, the oil content of certain microalgae surpasses 80% of the dry weight of algal biomass, and others have around 15–40% (dry weight), while palm kernel has about 50%, copra has about 60%, and sunflower has about 55%. The oil component accounts for 64.4 percent of the total lipid component. Biochemical, thermochemical, and direct combustion are the three types of biomass energy conversion reactions[6]. Fermentation, anaerobic, bio - electrochemical fuel cells, and other bioconversion processes may be further split into fermentation, anaerobic digestion, bio electrochemical fuel cells, as well as other biochemical conversion processes. Gasification, pyrolysis, or liquefaction are the three types of thermochemical conversion. the microalgae energy conversion mechanisms Biomass may be transformed into three different products, two of which are energy-related and one of which is a chemical feedstock. Because microalgae have a high water content (80–90%), not all biomass energy conversion methods can be applied to them. Direct burning of microalgae, for example, is only possible for biomass with a moisture level of less than 50%. Biomass with a high moisture content is more adapted to biological conversion.

1.3.Production Of Microalgae

A wide range of systems may be used to grow microalgae. A tiny fermenter, internally lit photo bioreactor, or box style water tanks are used for small size or laboratory scale growth. The fermenter utilizes four fluorescent lamps as external irradiation, with a degree of irradiation of 10,000 lx or 20,000 lx at the inner surface of the fermenter vessel, or alternative light distributors. One of the main benefits of utilizing an internally constantly illuminated photo bioreactor or a flat plate photo bioreactor is that contamination may be reduced by heat sterilization under pressure. Algae may be produced in open culture systems or closed culture systems for large-scale growth. Natural water (lakes, lagoons, and ponds) and manmade ponds or containers are the two types of open ponds. Shallow big ponds, tank, circular pond, or raceway ponds are the most frequently utilized systems.

1.4.Production Of Energy

1.4.1. Thermochemical Transformation

Gasification Gasification is a chemical process in which carbonaceous materials (hydrocarbons) are partially oxidized with air, oxygen, and/or steam at high temperatures, usually in the range of 800–900 C, to produce synthesis gas (syngas). A flow diagram of a microalgae system for low-temperature catalytic gasification of biomass for fuel generation.

A new power generation system based on microalgae has been suggested, which includes nitrogen cycling and low-temperature catalytic gasification of the microalgae. Elliot has also created a low catalyst gasification of high-moisture biomass. Without drying, rising biomass is gasified straight to methane-rich fuel gas. In furthermore, during the process, nitrogen in the biomass is transformed to ammonia.

Liquefaction Micro algal cell crystalizes obtained via centrifugation have a high moisture content and therefore make excellent liquefaction raw materials. Direct hydrothermal carbonization in sub-critical water quality is a method for converting wet biomass materials to liquid fuel.

1.5.Pyrolysis

Pyrolysis is the process of converting biomass to biofuel, charcoal, and gaseous fraction by warming it to around 500°C in the inert atmosphere or in the presence of a catalyst at a rapid heating rate (103–104 K/s) and a short gas residence time to crack the biomass into short chain molecules, which are then rapidly cooled to liquid. Slow pyrolysis methods were used in previous research, with a modest heating rate and a lengthy residence period. Longer residence periods may result in secondary cracking of the main products, lowering output and compromising biofuel characteristics. A low heating rate and a lengthy dwell period may also increase energy consumption. Fast pyrolysis methods for biomass have gotten a lot of interest in recent years since they can maximize liquid yields, and there have been a lot of studies done on them.

Fast pyrolysis has the benefit of producing a liquid fuel immediately. The conversion of biomass to bio-crude with an efficiency of up to 80% is possible when flash pyrolysis is employed. A fluidized bed rapid pyrolysis device in concept.

1.6.Hydrogenation

Hydrogenation is a reductive chemical process that adds hydrogen (H_2) to organic compounds, usually to saturate them. The procedure involves the addition of hydrogen atoms to a molecule's double bonds with the help of a catalyst. In the presence of a catalyst and a solvent, algal hydrogenation is carried out in an autoclave at high temperatures and pressures. To accomplish algal conversion and enhance the transfer of momentum, heat, and mass, contact must be made

between the gaseous phase (hydrogen and hydrocarbon phase), liquid phase (combination of solvent and liquid product), and solid particle phase (algal and catalyst). As shown in figure 1, From a sparger at the reactor wall, the gases reactant was bubbling through the liquid, and the solid particles were slurried with the liquid and supplied to the reactor. The gaseous or solid reactants dissolve in the liquid phase first and then diffuse towards the catalyst with the liquid reactant. All of these reactants after which interact at the catalyst's surface. To maintain a consistent liquid level inside the reactor as well as a stable composition in the water form, the liquid products, solid particles, and unreacted ingredients were constantly taken out. Unreacted gaseous reactants and products entered the space just above surface of the liquid as well as exited via a gas pipe.

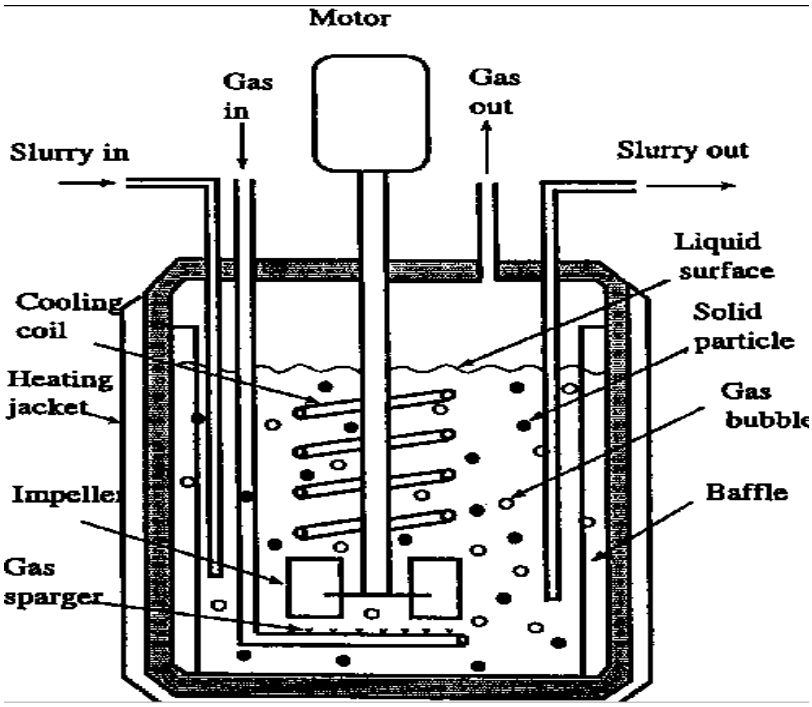

Figure 1: illustrate the Apparatus used for hydrogenation within an autoclave[7]**.**

1.7.Biochemical Transformation:

1.7.1. Fermentation:

Fermentation is the process of producing ethanol from microalgae. Microalgal cultivation, algal cell harvesting, slurry preparation, fermentation, as well as ethanol separation are all part of the process. Fermentation is widely used commercially to produce ethanol from sugar or starch crops in a variety of countries. The biomass is pulverized, and enzymes convert the starch to sugar. Yeast converts the sugar into ethanol. Distillation is an energy-intensive stage in the ethanol purification process. The following method may be used to make ethanol utilizing microalgal as a raw material. The starch of microalgae is liberated from the cells in the first stage, using mechanical equipment or an enzyme. When the cells start to disintegrate, yeast from Saccharomyces cerevisiae is introduced to the biomass to start the fermentation process. Ethanol is the end product of fermentation. The bioethanol is pumped out of the tank and into a holding tank before being fed into a distillation unit. Another study looked at the synthesis of ethanol via dark fermentation in the coastal green alga Chlorococcumlittorale. At 25 C, 27 percent of the cellular starch was destroyed in 24 hours under dark anaerobic circumstances, with cellular

starch breakdown increased at higher temperatures. Fermentation products included hydrogen, ethanol, acetate, as well as carbon dioxide. At 30 C, ethanol had a maximum productivity of 450 lmol/g-dry weights.

Figure 2: Illustrate the Diagram Showing Fermentation Process of Micro Algae

1.7.2. Transesterification

Transesterification is the process of replacing an ester compound's alkoxy group with another alcohol. An acid or a base catalyzes the processes in a homogeneous or heterogeneous catalytic process. The interaction of a fat or oil with an alcohol to produce esters and glycerol is known as transesterification. Glycerol and esters are formed when alcohol reacts with triglycerides. Biodiesel is the end product of the transesterification. The alcohol must be used in excess in order to get a high yield of the ester. Many studies claim that biodiesel may be made at home using basic procedures as well as equipment.

1.7.3. Applications of biofuels:

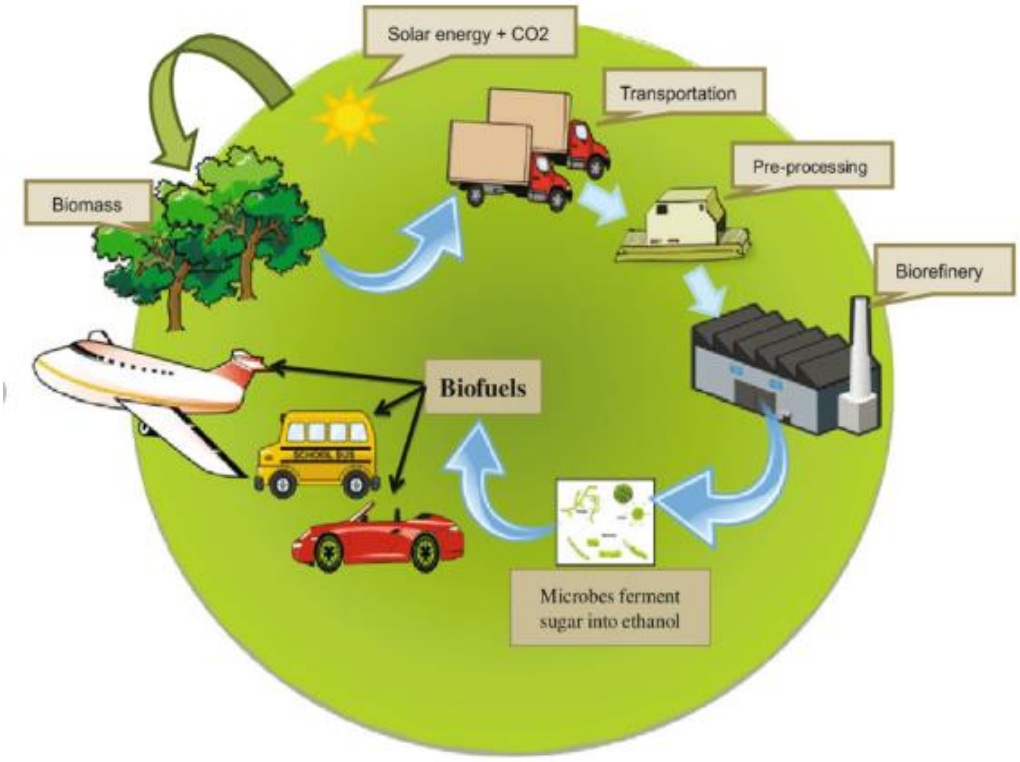

Figure 3: Illustrate The Major Application Of Biofuel.

LITERATURE REVIEW

Jeremiah David Bala et al. studied about Microalgae is regarded as among the most promising biofuel feedstocks. Because of their potential to decrease reliance on crude oil-based fuels and chemicals, interest in algae-based biofuels and chemicals has grown in recent years. Algae is the most appropriate and long-term feedstock for green energy production. However, a move to biofuels as an alternative product from algae has been accounted for by many difficulties connected with decreasing fossil fuel supplies as energy sources. Algae is a renewable energy source since it can repair greenhouse gases (CO_2) via photosynthesis and does not compete with food production. As a result, this chapter provides an overview of algae's potential for biofuel production, with a focus on macroalgae-based biofuels energy products derived from algae as the raw material. In a nutshell, algae are the most environmentally friendly fuel source available[8].

S.Kumar et al. studied about to encourage the development and use of biofuels, a wide range of regulations are in place, including policy goals, blending requirements, tax incentives, and other financial schemes. Biodiesel production in the area is led by Indonesia, while ethanol production is led by Thailand. The article examines these nations' biofuel policies, underlying causes, and prospects for long-term biofuel development. In these nations, favorable legislative and economic processes have played a significant role in the production, use, and market penetration of biofuels. Though each of these nations has seen some setbacks in their output, overall, biofuel production has risen, and an increasing trend is expected in the future if demand, consumption, mandate enforcement, and policy goals are met. The main motivation for these nations to seek biofuel production is not climate change. Sustainable biofuel production and dependence on second-generation biofuels, on the other hand, may enable these nations to convert their

development potential into economic income under carbon financing, thus addressing greenhouse gas emissions and climate change issues[9].

M.V.Rodionova et al. studied about In contrast to the limited nature, geopolitical instability, and negative global consequences of fossil fuel energy, it is becoming more apparent that biofuels may be a sustainable source of renewable energy. Biofuels are any energy-rich compounds produced directly via biological processes or obtained through chemical conversion of biomass from previous live creatures. Burning woody or cellulosic plant material and dry animal waste directly produces primary biofuels. Secondary biofuels are divided into three generations, each of which is produced indirectly from plant and animal matter. In this study, we discuss current advances in microbial biofuels production, including difficulties and possibilities, as well as prospective uses of microalgae as a biomass production platform. The search for novel bioenergy species, the optimization as well as improvement of culturing, genetic modification of biofuel-producing species, a full understanding of biofuel production mechanisms, as well as effective techniques for mass growth of bacteria should all be priorities in future biofuel research[10].

DISCUSSION

Many individuals mistakenly think that the material is exclusively used for transportation. Biofuel, on either hand, may generate hydrogen, clean oil, and even be used as a cooking oil. Biofuels can be used to replace a variety of energy sources, including vehicle fuel and central home heating. Among different plants such as palm oil, coconut, castor bean, and sunflower seeds, microalgae produce the most oil. Microalgae contain oil content ranging from 15% to 40% of dry weight, with some microalgae having as much as 80%. The total lipid component is expected to include 64.4 percent oil. Algae oil may be extracted using a number of techniques or a combination of techniques. Gasification generates combustible gases such as H_2, CH_4, CO_2, and ammonia, while pyrolysis provides biofuel.

CONCLUSION

Many individuals mistakenly think that the material is exclusively used for transportation. Biofuel, on either hand, may generate hydrogen, clean oil, and even be used as a cooking oil. Biofuels may be used to replace a variety of energy sources, including vehicle fuel and central home heating. Microalgae are a renewable energy source with significant CO_2 fixing potential. A significant amount of algal biomass is required for biofuel generation. Photo bioreactors or open ponds may be used to cultivate the microalgae. The biofuel may be utilized in engines and turbines, as well as in refineries as a feedstock. Ethanol is the fermentation product of microalgae. Ethanol may be used as a fuel or as a gasohol (100 percent alcohol). Algae oil may be turned to biodiesel using a transesterification method. The biodiesel product has primary properties that are very comparable to or compatible with regular petroleum diesel, and it may also be mixed with petroleum diesel in any proportion.

THE PLACE OF GENRES OF FOLKLORE IN MODERN LITERATURE AND THE ISSUE OF STUDY

Nilufar Shirinboevna Tosheva*

*Doctor of Philosophy in Philology (PhD),
Navoi State Mining Institute,
UZBEKISTAN

ABSTRACT

This article discusses the role of folklore genres in modern literature and the stages of their study in Uzbek and world literature.Modern Uzbek literature develops through the creative use of national values and folklore traditions. In the field of literature, there are new studies devoted to the study of the influence of folklore on written literature. Researchers of the new era are increasingly striving to find the root causes of the charm and charm of fiction at the basis of folk oral art. This interest requires the study of the relationship between folklore and written literature in a new direction.

KEYWORDS: *Folklore, Folklorism, Prose, Poetry, Analytical Folklorism, Narration, Myth, And Tradition.*

INTRODUCTION

Modern Uzbek literature develops through the creative use of national values and folklore traditions. In the field of literature, there are new studies devoted to the study of the influence of folklore on written literature. Researchers of the new era are increasingly striving to find the root causes of the charm and charm of fiction at the basis of folk oral art. This interest requires the study of the relationship between folklore and written literature in a new direction.

Studies of the relationship between folklore and written literature, conducted by literary critics, can be divided into two groups:

1.A study of the relationship between classical literature and folklore.

2. A study of the relationship between modern literature and folklore.

The research work carried out in the framework of the study of modern literature and folklore relations was also studied in groups by literary genre: a) studies devoted to the place of folklorisms in prose works; b) research on the artistic functions of folklorisms in poetic works; c) research on the stylization of folklorisms in dramatic works.

In fact, the issue of the history and essence of the study of folklore in Uzbek literature is considered as a separate object of research. It is also possible to classify the research work done in this regard in a different way from the point of view of time. Accordingly, if we look at the research, the relationship between the works of Alisher Navoi and folklore in classical literature is more studied, and the services of the well-known Uzbek literary critic N. Mallaev in this regard are invaluable. Literary critic Alisher Navoi studied lyricism and folklore in the epic "Khamsa". N.Mallaev's researches revealed that folklore motifs played a poetic role in the poet's work. Folk books about the heroes of the epics "Khamsa" are also commented on the myths and legends about them [1. 200-300]. Alisher Navoi examines the historical basis of his epics "Farhod and Shirin" and "Layli and Majnun" and gives examples of folk tales about the heroes of the work.Influenced by folk tales and fairy tales, the poet created new epics that perfectly express the adventures of "Farhod and Shirin", "Layli and Majnun" by poetic means. Literary critic N. Mallaev studied folklore of the XV century in the works of one writer.

The Main Findings and Results

Even after independence, attention was paid to the poetic analysis of folklore elements in the works of A. Navoi. Folklore in M. Narzikulova's epic "Sab'ai Sayyar" and the interpretation of Bahrom's plot in Uzbek folklore"[2. 5-15],T.Khojaev's dissertation on "Uzbek literature and folklore of the first half of the XV century" [3. 124] covers the motifs of folklore in the works of some representatives of our classical literature and their poetic functions.

The second group of classifications includes researches of G.Jalolov, N.Karimov, G.Muminov, O.Sobirov, O.Safarov, S.Askarov, M.Omilova, H.Doniyorov and S.Mirzaev on the issues of folklore and written literature [4]. In particular, in the article by Siddiq Askarov "Some issues of folklore in the works of Abdullah Qadiri" we see that the first examples of the writer's work have already studied folklore in detail. In this article, the researcher discusses the author's drama "The Unhappy Groom", "What does Toshpolat Tajang say?" his humorous story, his masterful use of simple forms of folklore in his novels "The Bygone Days" and "The Scorpion from the Altar".These folklorisms served as a powerful means to lift the reader's spirit, to express the joy and sorrow in his heart, and to alleviate it. The people's creative attitude to man and the world, their worldview, dreams and hopes are reflected in the examples of creativity created by the people. That is why the creation he created has immortal power. The influence of folklore on the written literature requires a great deal of care on the part of one to study the matter. In the above research, the harmony between written literature and folk oral art is shown from different angles.

Reading prose works created in written literature, we see the influence of folklore in the plot of a work of art, in the system of images, in the composition of the work. The elements of folklore used in the work of each artist fulfill a certain poetic function. The influence of folklore on the written literature is observed in the works of writers of all periods. It is clear from this that folklore is a literary-aesthetic process that can have a significant impact not only on the emergence of written literature, but also on its development and prosperity.

Oral creativity, created by our people, has always in its essence defended the interests of the working people. Folklore works reflect the dreams and aspirations of our people. Folklore can also be used in all types of written literature, including drama, poetry, and prose. Elements of

folklore are important to a work of art no matter what type is involved. From a scientific and theoretical point of view, all three literary genres are influenced by folklore.

The role of folklore in our literature and how it is used by artists has attracted the attention of many literary critics to this day. O. Sabirov analyzes the prose of Abdullah Qadiri, Oybek, G.Gulam, Komil Yashin in his study "Uzbek realistic prose and folklore". During his research, O. Sobirov focuses on the speech of the heroes in the works of Abdullah Qadiri, G. Gulom, Oybek, Kamil Yashin, the elements of folklore in the plot of his works.

Literary critic Marhamat Omilova's study, "Folklore Traditions in Uzbek Soviet Literature," focuses on the works [5. 110-124]of Gafur Gulam and Askad Mukhtor. The researcher focuses on the elements of folklore in the works of G. Gulom, such as "The Resurrected Dead", "Shum bola".Literary critic Askad Mukhtor's novel "Chinor" and its folklore were also widely emphasized during his research.M.Omilova commented on the novel "Chinor" and the legends that formed it, and commented on the role of legends in the composition of the work. The researcher also noted in his article that the author managed to ensure the true nationalism and philosophical depth of the work through the creative use of folklore traditions in his work [6. 7-12].

Professor G. Muminov in his doctoral dissertation on "Folklore in modern Uzbek literature" notes that in our literature there is a growing number of ways to retell folk tales and fairy tales in a poetic way [7. 44].Although the topic of folklore is currently poorly studied in dramatic works, G. Muminov in his research studies the motifs of folklore in some dramatic works. Izzat Sultan portrays the struggle of the peoples of Central Asia for freedom in the drama "The Unknown Man", which depicts the heroism of the people who fought against oppression for justice. In this drama, the playwright aims to show the participation of the people in such uprisings, using the popular story of prayer and the epic "Prayer" by Nurmat Bakhshi [8. 30].

Literary critic G. Muminov studied the role of myths and legends in the composition of works of art, their poetic function on the example of the works of poets and writers from the early twentieth century to the years of independence.

Literary critic D.Kuvvatova studied folklore traditions in Uzbek science fiction and studied folklore motifs in Uzbek fiction as an object [9.80 110]. Literary critic A. Ergashev in his research studied narrations from folklore motifs [10. 13-62]. His study, The Legend and Its Role in the Compositional Structure of a Fiction, provides a scientific basis for the narrative and its poetic function in the composition of a work of art, and the relationship between the narrative and the plot of a work of art.

M.Imamkarimova examines folklore motifs in the works of the writer in her research "National values in the works of Utkir Hoshimov" [11. 54-98]. In doing so, the researcher focused more on ethno-folklore and its role in the plot of the work of art.

In his research, Sh. Suleymanov conducted research on the expression of folklore motifs in detective stories. In his scientific work "The role of folk traditions in Uzbek detective prose" the researcher studies the motives of folklore at the heart of detective works in Uzbek literature. The object of research is the works of such writers as Olmas Umarbekov, Omon Mukhtor, Tohir Malik, F. Kilichev, M. Saibov, who created relatively perfect examples of Uzbek detective prose.

The literary critic first divides the detective works into two and examines the folklore motifs in the prose of the above creators [12. 70-115].

Sh. Doniyorova in the dissertation "Artistic and methodological peculiarities of Shukur Kholmirzaev's stories" [13. 30-128] the local calorie is in terms of the hero's uniqueness as well as national character and style aspects,the scientist studied the stories of Sh. Kholmirzaev "Freedom", "Man who flew into the abyss", "Old man", "Fatherland" and many others. These stories explore the national spirit and national character of the Uzbek people. Studying the stories of the writer, the researcher explores the places where the heroes lived, their national characteristics and signs, images of the customs of the people to which they belong.

Literary critic Mominjon Khalilov in his article "The role of folklore in the development of our prose" focuses on the works of Abdullah Qadiri in a humorous direction. From the author's "Kalvak Makhzum's memoir", "What does Toshpolat tajang say?" such as satirical works. The comic situation in G. Gulom's story "Shum bola" is also analyzed in this article.The article explores the tendency of the researcher to refer to the genre of folklore in our prose, the legends of devotion and duty used in the works of Olmas Umarbekov "My love", "It is difficult to be a man." The morning star in Hoshimov's story "Desert Air" is illustrated by the legends about the Konkus river in "Spring does not return".

Folklore has been the basis for the creation of rare examples of written literature for centuries. There is an artist who truly feels artistic creativity, and people use their oral creativity to ensure the eternity of their creativity.

Folklore and written literature are always in contact with each other. Folklore has served as an inexhaustible treasure for literature of all times. Many fairy tales, proverbs, legends, anecdotes, legends based on folklore formed the basis of works of art created in written literature.

Reflecting in art traditions, rituals, national values, joys and sorrows of their compatriots, creative people strengthen in the hearts of the younger generation respect for the past and the homeland of their ancestors. If the younger generation is brought up in the spirit of love for the national heritage created by their ancestors, for the centuries-old traditions of their ancestors, it is natural that they are inspired by national traditions and rituals and strive for creativity, development and prosperity.

The author Sabir Onar's work "Bibisora" observes and analyzes a number of Uzbek traditions. The day after the wedding of Suyundik and Tolgonoy, one of the heroes of the work, there will be a "Yuz Ochar" ceremony. According to this ceremony, the boy, who had not yet reached the age of prayer, would open the bride's face with a fat spoon. "At the insistence of the women, I poured half a bucket of oil into the burning fire on the plane. Otherwise, the bride will have fat legs. The bride will bring blessings to this house" [14. 13].The above ceremony has been preserved by our grandmothers for many generations. When we generalize such ethno-folklorisms used in prose, their function for the plot of the work of art is as follows: a) reveal the character of the protagonist in the work; b) embodying the portraits of images in the eyes of the reader; c) to show that the protagonist is connected with society and social life; d) to reflect the aesthetic views of the protagonists of the work on social life and their spiritual world; e) to be able to see the art of the work realistically and feel it from the inside.

The narration of the writer Nazar Eshanqul in “The Son of the Gorge or the Water of Life” belongs to the complex form of folklore and belongs to the analytical type. The legend is about a saint who is narrated by the uncle of the protagonist of the work. “Analytical folklore has been used as a literary factor in the Mayan episode to reveal its inner dramatic collections in the spirit of the protagonist” [15. 50]. Through the legend of the “Saint”, the creator tries to reveal the inner college in the psyche of the protagonist. This narration is only used to reveal the psyche of the protagonist.

CONCLUSION

Throughout the literary process of all times, the study of the relationship between written literature and folklore has been an important topic of literary criticism. The influence of folklore comprehensively enriches written literature. In addition, the work served to further reveal the character of the main characters, to fill in the lines characteristic of the portrait of the main character.

Folklore is the spiritual heritage of our people. It serves as a fountain for works created in each period.

ABSTRACT

In this article, the world practice of using factoring in different countries was considered. Pros and cons of introducing factoring using statistical data.Based on them, ways to solve these problems were given, as well as the application of factoring in the Republic of Uzbekistan, taking into account world practice.

KEYWORDS: *Factor, Factoring, Commercial Banks, Factoring Companies, Business Entities, Accounts Receivable.*

INTRODUCTION

Factoring is widespread in many countries as one of the most important sources of external financing of business entities, the convenience of which is well perceived from their sides. In particular, the fact that the funds financed directly depend on the total amount of accounts receivable and not in the form of loans, this opens up the possibility for them to replenish working capital and ensure the turnover of working capital for business entities. In general, despite the fact that the global economy and the financial situation have lagged far behind due to the pandemic, factoring indicators remain unchanged. So, factoring is a financial instrument and a complex financial product provided by a factor (commercial bank) to a supplier client in exchange for the assignment (sale) of receivables, which includes supplier financing, administrative management, debt collection, as well as elements of information, insurance, accounting, legal, and other services.

According to SuzanaBaresa, Sinisa Bogdan [1], in general, between 2004 and 2010, the factoring rate between countries (with the exception of a slight decrease in 2008) showed growth rates, especially in 2010, when domestic factoring increased by 20%, and external factoring by 34%.

According to a World Bank study on factoring in a number of European countries, the share of factoring operations in relation to GDP is directly related to the recognition of the type of financial services in legislation. According to Marie H.R Bakker et al., [2] ... in many countries, the overall share of the factoring market size relative to GDP is relatively high. For example, in Italy, Great Britain and Portugal, this figure is 12-15%. In Germany it is 3%. In general, economists at the international level analyzed factoring legislation and came to the following

conclusion ... in countries where legislation and control over factoring are strict, the development of factoring is at a low level.

According to the director of the Department of Trade Finance of the Moscow Credit Bank, N. Bakhova [3] ... during the pandemic, a sharp increase in demand for telecommunications equipment from abroad, preventing the risk of late arrival of products, led to a sharp increase in demand for factoring. According to I. Lysenko, Director General of "Sber Factoring" [3], in the context of a pandemic, international factoring practice does not allow exporters to pay for non-resident products and becomes one of the reliable sources of its financing. However, for importers (suppliers), this is one of the ways to optimize accounts with non-residents and extend payment terms.

ANALYSIS

The current form of factoring originated in Great Britain in the XIII century and became a common type of financial service in the development of trade between its colonies. The UK is currently the world leader in factoring turnover, as evidenced by the fact that the annual turnover of factoring averages 325 billion euros, accounting for 12-15% of GDP, of which 300 billion. Euros are internal factoring operations. (See Table 1.) The share of factoring in commercial banks is 93%, and the remaining 7% are factoring companies. Providing a wide range of factoring services, where many large commercial banks have opened their subsidiary factoring companies, including Royal Bank of Scotland and Lloyds TSB, etc. In the UK in 1999, more than 24 thousand economic entities used factoring, which employed more than 500 thousand workers. [4]

Great Britain	286	188	196	226	268	291	308	350	376	327	324	320	329	273	121

After the collapse of the Soviet Union in 1991, the countries of Eastern Europe (Poland, Czech Republic, Hungary, Romania, Bulgaria, Slovakia, Slovenia) quickly moved from a planned economy to market mechanisms. Of course, this transformation process was not easy. It caused a shock in the economy, a decline in production, unemployment, and other problems. But the countries of Eastern Europe quickly overcame these difficulties and managed in a short time to achieve the economic indicators of their Western partners, which they have achieved for many years. The main driver that made a great contribution to the development of Eastern European countries was the inflow of foreign direct investment. If you look at the figures, only from 1990 to 2008 did Poland receive 111 billion dollars, the Czech Republic-75 billion dollars, Romania-58 billion dollars, and Hungary, 52 billion dollars [6]. Undoubtedly, this economic growth has also influenced the development of factoring. (Table 1). In recent years, Poland has been ahead of not only Eastern European countries in the development of factoring, but also developed European countries. The average growth of factoring is 8% of GDP. This is 248,701 million Polish zloty (55,638 million euros). (Table 1)

In Poland, factoring is considered as an alternative to credit services. This leads to a reduction in overdue debt with prolonged financing of accounts receivable. In turn, debt management leads to an increase in the liquidity of economic entities. It is for these reasons that, unlike in other European countries, factoring is widespread in Poland. In the Polish Civil Code, factoring is not part of banking services, therefore the Central Bank of Poland does not control factoring operations, but the factoring market is regulated by the norms of the International Convention [1] (UNIDRUA) [7].

In Poland, internal factoring is well developed, accounting for 80% of the entire market. As a result of our research, it turned out that the practice of factoring without recourse is mainly developed in Poland. In the Polish factoring market, customers (suppliers) risk non-payment of receivables and try to conclude factoring agreements with factoring companies or commercial banks, mainly agreements without recourse. The main reasons for factoring without recourse are: the risk that in practice falls on the factoring company (commercial bank). That is, after the factor finances the supplier, the accounts receivable that will appear between them and the fact of non-receipt of these funds from the buyer is very large, and in the case of factoring without the right of recourse, commercial banks bear all the risks. In other countries of the European Union, it's all the opposite, that is, the financial risk arising in the factoring process will rely mainly on the client (supplier) of the factoring company (commercial banks). You can see this comparison in the table below. (Table.1)

2. TABLE. COMPARATIVE TABLE OF THE SHARE OF FACTORING IN POLAND AND THE EUROPEAN UNION IN 2014-2015 [1]

Indicators	Poland (billion. euros)				European Union (billion. euros)			
	2014		2015		2014		2015	
Total factoring	34	Share in %	35	Share in %	1462	Share in %	1557	Share in %
Domestic factoring	30	86,93	28	87,79	1214	89,59	1263	80,83
Non-recoursefactoring	17	57,64	14,84	53,64	497	41,19	282	54,25
Recoursefactoring	13	42,32	13,6	41,06	715	58,81	798	45,75
International factoring	4	13,07	7	12,79	247	18,41	293	19,17

In Poland, factoring companies widely use the practice of insurance when acquiring and financing the rights of receivables. The above factors led to the development of factoring without the right of recourse. In conclusion, we can say that the practice of factoring without the right of recourse is suitable for business entities that are financially stable. According to the Polish Factoring Association, before the 2008 financial crisis, commercial banks dominated factoring operations in Poland. However, by 2020, the number of non-bank credit organizations practicing factoring will have doubled to 43 companies. [7]

According to the Central Statistical Office of Poland, 90% of economic entities that use factoring are small and medium-sized businesses with an average turnover of 1 billion rubles. zloty (approximately $257 million)

Undoubtedly, an important factor is the study of foreign experience in the development of factoring and its application in the factoring market of our country. Foreign experience of factoring in our republic would make a significant contribution to the development of factoring, as well as the elimination of existing factoring problems. In this regard, it is best to study the experience of the Russian factoring market. Since they are historically separated from one system, economic, spiritual, and social proximity also play an important role in the application of these factors. Currently, the factoring market in Russia is developing rapidly. Largely due to the ratification of the International Convention (UNIDRUA) in 2014. [8] and the inclusion in the Civil Code of a separate chapter on factoring in 2018, entitled "Financing in exchange for the waiver of a monetary claim in favor of another person" [9], which is one of the key factors in the regulatory framework of the Russian Federation. Even with the introduction of economic sanctions in 2014, as well as a sharp drop in prices in the world market for oil and gas (the price of 1 barrel of oil fell from $107 to $25 per barrel in 2014), could not have a big impact.

The volume of factoring operations in the Russian Federation continues to grow. Although there was a decrease in export-import operations in 2020 due to the impact of the pandemic, this factor did not have a significant impact on factoring operations. For example, in 2019, the volume of international factoring operations amounted to 21.2 billion. In 2020, it will double to 40 billion. (600 million US dollars) and will triple to 60 billion by 2021.RUB (approximately $810 million) [3]

Although international factoring in Russia began to develop on a large scale starting in 2018, it is much lower than in other developing countries. For example, in many developed and developing countries, the share of international factoring is 15% of the total volume of factoring, and in Russia it is only 1%. In the context of the pandemic, the remote work of economic entities led to the extension of their payment contracts, which led to an increase in accounts payable and receivables between enterprises and organizations. This factor has led to an increase in demand and interest in factoring in business entities. In 2020 alone, factoring funding increased by 24%, and their portfolio increased by 37% to 1.1 trillion rubles ($14.670 billion). [11]

RESULTS AND DISCUSSIONS

Germany is one of the leading developed countries in the world, but the practice of factoring is not sufficiently developed. As a result of our research, it turned out that until recent years, there were legal restrictions on the implementation of factoring in Germany. In the legislation of the Federal Republic of Germany, factoring is understood as a contract of sale, a debt obligation arising in the process of selling goods or services. If banks specialize in providing factoring services, they must obtain an additional license in accordance with the provisions of German credit legislation in addition to the banking license. This means setting an additional limit for commercial banks to perform factoring operations. Taking into account the practice of applying factoring in Germany, we conclude that the legislation regulates factoring activities so

thoroughly, and this hinders the development of factoring in those countries that are not mediocre.

Factoring in the UK is developing at a high level. What is the reason for this?

Firstly, the practice of factoring is not regulated by the state. In English law, factoring operations are understood to mean the refusal of unpaid debt claims in favor of another person between the parties (supplier, buyer, factoring company or commercial bank) arising as a result of commercial credit, accounting, information, insurance, legal and other services for the sale of goods and services. Thus, factoring activities are carried out within the framework of general civil law regulating the activities of economic entities and do not require a special permit (license). In addition, British banks, insurance companies and other financial institutions can carry out factoring operations on the basis of existing permits to carry out factoring operations as part of their activities.

Secondly, accounts receivable management. For example, if a company has 3-5 debtors, there will be no problems with debt management, and even one employee will be able to control it. However, if the number of clients is in the thousands, then this will lead to a significant increase in management costs. Analyzing the growing market, British companies have come to the conclusion that it is not necessary to have a large number of employees to collect and control debt, since a factoring company (commercial banks) will make it all much easier.

Thirdly, the culture of risk insurance. An important feature of factoring is that it is a set of services that covers not only the financing of working capital, but also the risks of default by debtors. The British prefer to ensure their financial risks, even in small amounts, then to suddenly lose the entire amount. That is, factoring operations in the UK are permanently insured.

Fourth, popularization of factoring. In the UK in the 70s and 80s, constant and persistent work was carried out to provide extensive information about factoring and improve the image of factoring, and this has borne fruit. Gradually, factoring companies were formed in society, not as an extreme measure of financing economic entities, but as a convenient and effective financial tool for business development.

Currently, commercial banks in Uzbekistan use factoring without recourse, mainly for clients who have been considered reliable customers of the bank for many years. Commercial banks in the Republic of Uzbekistan are not interested in attracting representatives of small and medium-sized businesses to use factoring. Even if they apply to commercial banks for financing for factoring, they are rejected by the banks because they are skeptical about the financial condition of most of them. In world practice, one of the "golden rules" of factoring is the financing of small and medium-sized businesses. After all, factoring is a convenient type of financial service for small and medium-sized businesses in all respects. In our opinion, if the Government applies sufficient measures for the development of factoring (regulatory) and commercial banks, will contribute to the development of factoring among small and medium-sized businesses, it is not only the development of this type of financial services, but also the development of other sectors of the economy through the circulation of working capital.

Above, we studied the development of factoring without recourse in Poland and its relationship with the European Union in 2014-2015, studying the above hypothesis at the moment and to answer the question: we compared the same table, that is, the turnover of factoring in Poland and in the EU for 2019-2020. In our opinion, over the past five years, the ratio of factoring without the right of recourse in the EU has also developed. (Table 3)

TABLE 3 COMPARATIVE TABLE OF THE SHARE OF FACTORING IN POLAND AND THE EUROPEAN UNION IN 2019-2020 [5]

Indicators	Poland (billion euros)	European Union (billion euros)

	2019		2020		2019		2020	
Total factoring	66	Share in %	63	Share in %	1976	Share in %	1844	Share in %
Domestic factoring	55	83.3	52	82.5	1592	80.6	1483	80.4
Non-recoursefactoring	33	60	28	54	400	51	300	47
Recoursefactoring	19	40	17	46	200	18	100	16
International factoring	11	16.7	11	17.5	383	19.4	361	19.6

The development of the factoring market in Russia is one of the leading among the CIS and Eastern European countries. (Table 1)

In our opinion, there are several reasons why the growth dynamics of the factoring market in Russia has not changed even during the economic downturn (2014-2016):

Firstly, the adoption of regulatory legal acts on factoring (ratification of the UNIDRUA International Convention);

Secondly, the suspension of the provision of low-interest and short-term loans from foreign banks due to economic sanctions has increased the demand for factoring services in the domestic market as an alternative source of financing;

Thirdly, the transition of factoring contracts to an electronic format;

Last but not least, the gap in interest rates between commercial bank loans and factoring interest rates has decreased over the years from 10% to 6% in 2019. [11]

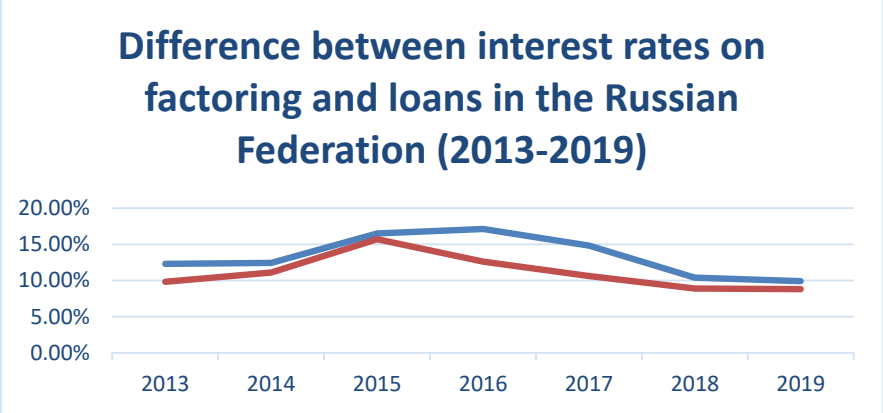

Figure Difference between interest rates on factoring and loans in the Russian Federation (2013-2019). [12]

CONCLUSION

In the international practice of factoring, no country can compare with another in terms of the volume of factoring operations. After all, the way each state adopts the practice of factoring in its own legislation may have a positive or negative impact on the development of factoring.

As mentioned above, the current development of factoring in the UK is a financial architecture built on four pillars. To the question of factoring influencing its development in one of the developed countries of the world and is it possible to get a model of its direct development in the factoring market of Uzbekistan!? According to article 750 of the Civil Code of the Republic of

Uzbekistan, in practice, a license is required for factoring in Uzbekistan. However, after the repeal of the Regulation "On the procedure for conducting factoring operations by commercial banks on the territory of the Republic of Uzbekistan" by Order of the Ministry of Justice of the Republic of Uzbekistan No. 3293 dated March 31, 2021, in our opinion, it opened up wide opportunities for commercial banks and factoring companies.

Secondly, in our opinion, it would be advisable for the implementation and management of factoring operations to be provided only by the parties of factoring companies or commercial banks. In addition, if factoring operations were performed on digital information devices, this would further contribute to the development of factoring.

Fourth, in our republic, as in the UK, large-scale work should be carried out, the promotion of factoring among economic entities. In our opinion, since many business entities currently have no idea about factoring, it is more convenient for them to get a loan from a commercial bank than to give the right to receivables to commercial banks and get a quick loan. In order to ensure the convenience and opportunities of factoring practice for business representatives in our country, commercial banks need to carry out the following work:

* Disseminating information about factors and broad advertising in the media and among the general public;

*Meeting directly at the location of a large business and informing them about the convenience of factoring;

* Provision of factoring information to clients via the official website, mobile application, and commercial bank offices;

*Comprehensive retraining of bank employees for factoring operations

In conclusion, we note the convenience of factoring, especially the rapid adaptation to changing market conditions, the fact that factoring is stable in the world during the current pandemic: our country has great potential for factoring operations. However, it is necessary to make greater use of these opportunities—to eliminate existing regulatory and legislative barriers to factoring operations and financing, and to further increase the prestige of international factoring in order to make it more acceptable.

12. According to the results of our research, the determination of factoring rates by commercial banks in Uzbekistan is mainly related to the refinancing rate of the Central Bank. For example, the central bank's refinancing rate currently stands at 14%, while commercial banks' lending rates average 24% for legal entities. Based on the same rate, the factoring rate is 6% for a period of 3 months. Factoring interest rate = 24 / 4th quarter = 6%

DRONE TECHNOLOGY IN THE MINING INDUSTRY: A COMPREHENSIVE REVIEW

Mr. Rishi Sikka*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: rishisikka.ec@sanskriti.edu.in

ABSTRACT

Drones have been employed for a range of civilian and military purposes and tasks, including unmanned air vehicles (UAVs) and micro air vehicles (MAVs). Depending on the kind of operation, these unmanned aircraft systems may carry a variety of sensors, including acoustic, optical, chemical, and biological sensors. The purpose of this article is to give a thorough overview of drone technology and its applications in the mining sector. Drones have sparked increasing interest in the mining sector for regular tasks. 3D mapping of the mining environment, ore control, rock discontinuities mapping, post blast rock fragmentation measures, and tailing stability monitoring are just a few of the uses available. The article provides an overview of commercially available drone types, specs, and uses for mining applications. Finally, the research requirements for developing and deploying drones for underground mining applications are addressed.

KEYWORDS:*Abandoned Mining, Drones, Remote Sensing, Surface Mining, Underground Mining.*

INTRODUCTION

Researchers have concentrated on the design optimization of drones to improve the performance and efficiency of drones, which has resulted in the creation and manufacturing of different kinds of aerial vehicles with varied capacities. Aerial vehicles have been used for industrial purposes since the nineteenth century. Balloons were employed to capture photographs for distant sensing applications around 1860. Pigeons equipped with a breast-mounted aerial camera were employed for photography in 1903. Aerial torpedoes, which are considered the forerunners of drones, were created at the start of World War I. Academic and industrial groups across the globe have been paying more attention to research and development of unmanned aerial vehicles in recent years. Drones are categorized in a variety of ways depending on their configurations and the purpose they are serving. Fixed-wing, flapping-wing, rotary-wing, tilt-rotor, ducted fan, helicopter, ornithopter, and unusual kinds are among the nine categories of drones [1][2].

Drones offer a wide range of capabilities that may be used in both military and civilian applications. Drones have been integrated into civic activities as a consequence of these

capabilities and the need for unmanned technology. New unmanned aerial vehicles are being developed to help achieve this goal, and they can conduct a range of tasks in a number of situations. Drones are used in a wide variety of civilian applications, including search and rescue, surveillance, firefighting, weather monitoring, surveying, power infrastructure monitoring, and urban planning and management, to name a few. Drones have also been used for ecological and environmental monitoring, species distribution modeling, population ecology, and ecological monitoring and conservation. Drones are also used in archeology and cultural heritage, human and social understanding, personal and business drones for photography and videography, and even delivery services [3].

Unmanned aerial systems have also been utilized effectively in a variety of sectors, including agriculture, oil and gas, construction, environmental protection, mining, and so forth. Drones have recently piqued the mining industry's interest for routine operations in both surface and underground mines [4]. The goal of this research is to look at how drone technology is being used in the mining sector. Previous research and information from businesses that offer drones to the mining industry are investigated for this aim. The use of drones in surface and subsurface mines is discussed in this article. Drones' use in abandoned surface and subterranean mines is also discussed. In addition, the most frequently utilized sensors on mining drones are discussed. The difficulties of utilizing drone technology in deep mines are addressed, as well as possible solutions. The use of drones in mining operations has two major benefits. Drones outfitted with various kinds of sensors, for example, may perform a rapid examination of an area in an emergency or to identify hazards [5]. Second, drones may be used to examine and unclog clogged box-holes and ore-passes. Drones may also be used to check blockages, deliver explosives, and transport packages. Mines are often found in large, isolated mountainous regions. As a result, monitoring mines and related infrastructures is a difficult job that requires a large amount of personnel. As a result, conventional techniques of monitoring mines are time and expense intensive.

Drones may be useful in monitoring, surveying, and mapping the area around mines if used correctly. Drones may be used to monitor mine operations and topographical changes in the mining region, which can lead to mine planning and safety guidelines. A drone equipped with a hyperspectral frame camera was utilized to monitor the safety of the production pit in, for example. In open-pit mines, slope angle optimization is critical for lowering production costs, increasing mining efficiency, and recycling resources[6].

Monitoring point displacement and 3D mapping of open-pit slope zones using a combination of terrestrial laser scanning and drone photogrammetry. They also kept track of mine inventories and developments in the mining area. Collecting geotechnical data from difficult or impossible to access regions is one of the mining industry's biggest challenges. In addition, terrestrial LiDAR technology could be used to map discontinuity for slope stability. Due to the small scan angle of LiDAR technology, however, “shadow zones” or gaps in data are frequently produced[7]. Drones, on the other hand, can be used to take photos and make measurements by analyzing overlapping photographs. Using drones to conduct a topographical survey in an open-pit mine to determine the direction of discontinuity on the surface of a rock slope. Another challenge in the mining industry is determining the site's engineering geology.

Engineering geology entails the mapping of outcrops, strikes, dips, feature notation, and names, all of which contribute to the site's characterization. Outcrops can be photographed in detail by drones. However, most of the time, the results must be double-checked using a human survey. New image processing algorithms allow for the identification of rock types, strike, faults, and dips, reducing manual labor significantly. Blasting is one of the activities that is commonly repeated in the mining industry. Drones could be used to inspect the safety risks associated with blasting. Rock type, geology, topography, geometry, borehole location, and other parameters that

can be controlled by drones are important in blasting design. In addition, using drones in blasting operations provides new low-cost data. Drones were employed to examine the size of rock blocks before and after blasting[8]. Drones were also used to monitor dust particles following blasting operations in an open-pit mine in another instance. Furthermore, dust particles from mining operations and tailings have a major environmental impact on the ecosystem around mine sites, which may be mitigated by monitoring and regulating mine and tailings moisture. Mining is a labor-intensive activity that requires large expenditures to guarantee worker safety and avoid stockpile pilferage. Mining firms are always looking for innovative ways to save costs and boost production, profitability, and worker safety[9].

This may be accomplished if mining activities are meticulously planned, assets are routinely examined, and the mining site is constantly monitored. Traditional techniques, on the other hand, are insufficient to comply with increasingly severe environmental and labor laws. Drones have a variety of uses in mining, including mine surveys, inventory management, stockpile estimate, and hot spot identification, among others. Drones may be used to scan mine sites and give comprehensive information about them before beginning mining operations, as well as to record their progress so that changes in the site can be seen over time. Drones can access hazardous, hard-to-reach locations to provide improved mining planning information. Drones may be used in coal mines to identify hot spots in coal stockpiles, allowing people to evaluate possible spontaneous combustion regions and take preventative actions. Watershed management, blast planning, haul-route surface improvement, and emergency response may all benefit from drones[10].

DISCUSSION

Thermal sensors on drones are used to record variations in the spatial and temporal surface moisture content of iron mine tailings in the study. Analyzing the connection between moisture content and mine tailings management, on the other hand, may be beneficial to mine tailings management. Drones can help with automation in the mining sector by delivering visual and other kinds of sensor data. Drones, with their excellent maneuverability and low cost and maintenance, can provide a significant benefit to the mine by surveying large areas in a short period of time, as opposed to traditional methods that rely on human labor. They can provide necessary information in areas where there are health and safety risks, such as on slopes or in unstable cavities. As a result, mines are now a safer place to work than they were previously.

A drone to fly over an abandoned mine in South Africa in order to reopen it. The drone's financial worth was determined, as well as its sensitivity and risk. The drone used was able to photograph the entire targeted mine, including images of damage and infrastructure. Drone technology was used at the University of Queensland to investigate the characterization of blasting plumes. Drones could accurately detect blast plumes to a concentration of 1 mg/m3. The data from the air quality sensor and the autopilot were combined to provide an airborne particles characterization in time and space that had previously been unavailable without the use of a drone. The most difficult aspect of this study was deciding which sensor to use for dust monitoring with drones. In an open-pit mine, a drone was utilized to assess fracture orientation. There were three major stages to this study. The drone first photographed the fractures. Second, using structure from motion (SFM) software, a three-dimensional (3D) point cloud was created (a point cloud is a collection of data points in space).

Third, in order to predict fracture orientation in an open-pit mine, an image processing method was developed. They utilized an Aeryon Scout multirotor drone to carry a 100-gram camera for video and picture capture. In 2013, a three-dimensional point cloud of the surface mine was obtained using the Aeryon Scout drone. The battery was placed on top of the drone in this study, while the payload was placed at the bottom. The drone had GPS, a sonar system for altitudes

greater than 2 to 4 meters, a pressure altimeter for range altitudes that sonar couldn't properly support, a temperature sensor, a three-axial magnetometer, and a three-axis gyroscope for navigation. Data was collected and kept in internal storage, ready to be retrieved once the operation was completed. The altitude, speed, location (latitude and longitude), and camera orientation (pitch and yaw) are all recorded in the log file generated by this drone. A radio modem with a range of 3 kilometers was used to link the Aeryon Scout drone to the base station. A multi hop emergency communication system was proposed in to aid miners and rescue teams in emergency situations while also increasing mining productivity. The plan was to utilize a drone as a wireless communication framework called Sky Help to monitor mining activities and assist with search and rescue operations in deep open-pit mines. To evaluate the concept, MATLAB was used to run a simulation. There are several marketed drones that have been used by businesses for surface mining applications, in addition to the studies and testing carried out by researchers in the use of drones in mining sectors. Sense Fly is a Parrot Group commercial drone company. This company creates both the hardware and software for collecting and analyzing aerial data with drones. The following is a list of Snesefly's general specifications. Inventory tracking (calculating stockpile volumes, site surveying), traffic management (haul roads, loading floors, and stockpile location optimization, blast planning), water management (accurate management of tailing dams, watersheds, drainage basins assessment, and mapping the potential flow of water base on-site current topography), and collaboration (improving operational efficiency) are some of the applications of the Sense Fly drone.

The business is a commercial drone cloud software platform that is particularly compatible with DJI drones. For a number of sectors, including mining, this firm offers software for aerial data processing by drones. The program can create a 3D model of the region, a contour line map, an oil mine inspection, and a volume estimate for stockpiles. Drone Deploy claims to have mapped and analyzed more than 30 million acres in over 160 nations, and the company provides both drone hardware and software for use in the mining sector. The Kespry Company's drone properties. Kespry Company provides services to the mining sector such as monitoring waste-rock and ore stockpile inventories, producing cut-and-fill reports for dragline operations, assessing slope stability on active high-walls, reclamation planning, and verifying blasting pattern sites. The Kespry 2s drone produces images with a resolution of 0.5 cm per pixel. Due to the short flight time of multirotor, Kespry equipped the drone with a field swappable battery. This drone's obstacle avoidance is about (50 m) forward-facing, thanks to its LiDAR sensor. Propeller Aero develops software for aerial data analysis and collects aerial data with a customized DJI Phantom 4 Pro (P4P) drone. Propeller Aero's DJI drones have the following characteristics. Track the status of the mine, volume measurement tools for stockpile and pit volumes, plan blasting and extraction, monitor protected areas and avoid environmental fines, track progress against design, safety inspection, and keeping haul road grades consistent are just a few of the services provided by the Propeller Aero package for the mining industry.

The Phantom 4 RTK can capture high-quality images with total vector distortion of (2.1 cm). Using multiple independent checkpoints across the site, the propeller drone demonstrates accuracy of 3 cm or less. Quest UAV develops software for aerial data analysis and collects aerial data with fixed-wing drones. Table 4 shows the properties of the Quest UAV drone. These drones can help with a variety of tasks in a mining operation. Over areas, the drone has a 3.2 cm accuracy. Due to the difficulty of landing fixed-wing drones, Quest UAV uses a parachute to ensure a safe landing. In addition, you can launch by hand, using a specially designed air dock, or using a zip line. In addition, Quest UAV drones can be outfitted with a variety of payloads. A multirotor drone for aerial data collection, a site base station that uses GPS and GNSS to collect accurate coordinates, and data management software. Sky catches developed the Explore-1 drone, which is based on the DJI Matrice M100 drone and produced by DJI.

The Explore-1 drone's general characteristics. With the help of Sky catch drone data, Komatsu attempted to make the earthwork machine autonomous. To find patterns and improve data outputs, they used machine learning and deep learning. Priories was one of the first companies to provide mining companies with aerial data. This company makes both drone hardware and software for aerial data collection and analysis. The following diagram depicts the general characteristics of Prioria goods. Aerial imagery, mapping, stockpile volume calculation, and pipeline and utility inspections are all performed by these products. This company's fixed-wing drones are tube-launched and hand-launched. The vertical volume calculation precision is 4 cm, and the ground sampling distance precision is 1.4 cm. 3D Robotics makes aerial data analysis software that is compatible with Yuneec and DJI drones. The general specifications of 3D Robotics drones. Geo-referenced maps and point clouds for mineral exploration, calculating the volumes of individual stockpiles, tracking inventory over time by calculating the volumes of individual stockpiles in every flight, improving site planning and coordination by pre- and post-blast surveys, mitigating project risk, and remote access to mine information are all services provided by 3D Robotics aerial scan. Land surveying, construction, agriculture, transportation, telecommunications, asset tracking, mapping, utilities, mobile resource management, and government are among the sectors for which Trimble Company offers positioning technology. However, recently, this company applied drone technology for aerial data collection and analysis. The technical specifications of this company's multirotor drones. The Trimble drones can provide boundary and topographic surveys, survey-grade mapping, power line modeling, field leveling, site, and route planning, progress monitoring, as-built surveys, resource mapping, disaster analyses, volume determinations, topographic contours, 3D surface models, and ortho photographs for mining industry.

Precision-hawk software for aerial data analysis and uses other company’s drones for aerial data collection. The specifics of DJI multirotor drones and birds-eye-view fixed-wing drone, which is used by Precision-hawk Company. The software of this company provides the volume measurement tools for the pit, stockpile, and similar structure for the mining industry. In addition, outputs of the software could be useful in monitoring, planning, reports, safety and compliance, oversight, and reclamation. This company uses various kinds of sensors on the drones for aerial data collection. Sensors, such as thermal for tracking the relative temperature of the land and objects, multispectral for capturing near-infrared radiation and ultraviolet light which is invisible to human eyes, hyperspectral for identifying minerals, vegetation and other materials, LiDAR for collecting high-quality evaluation of natural and human-made objects, visual for capturing high-resolution aerial images, and video for live streaming and capturing video to on the ground devices can be integrated into the drones .

Pix4d uses images taken by drones, hand, or plane for data analysis by using the photogrammetry method. The software of this company is compatible with a variety of drone company products including DJI, Parrot, and 3DR. The services for the mining industry by Pix4d Software Company are as follows: (1) supporting blasting operations by locating boreholes, (2) monitoring blast sites without putting people in danger, (3) measuring stockpile volumes and excavated materials, (4) Pit mapping, and (5) toxic tailing dam mapping. It has been claimed that drone mapping could be performed in 20 percent of the traditional mapping method time, without disrupting traffic. Micro drones produce both drone’s hardware and software for aerial data collection and analysis. The micro drone's specifications. Drones and software in the package can map the deposit site, survey the mine, explore minerals, monitor stockpile volume, track equipment, and take time-lapse photos. Sensors such as multi-spectral, thermal, LiDAR, and methane gas detection could also be added to the drone for inspection purposes. Drone positioning is done using GPS, and data post-processing is done using aerial triangulation. For aerial data analysis and collection, this company develops both software and drone hardware.

This company's software and drone package can provide stockpile volume, pit contour maps, hazard detection, anomaly detection, and topography surveying in the field without interrupting operations. Delair Company's DT18 Mapper drone package was used by one of the largest American copper and gold mining companies to conduct weekly topographical surveys for calculating production capacity and creating digital surface models of the copper mine at Tenke fun gurume (TFM) in the Democratic Republic of Congo's Katanga Province. Drone use in underground mines has been limited despite advances in drone technology. This is due to the difficulty of using drones in underground mines. Drones flying in harsh underground environments face numerous challenges. Flying a drone in underground working areas is difficult due to confined space, reduced visibility, air velocity, dust concentration, and the lack of a wireless communication system. Furthermore, a drone operator's access to inaccessible and dangerous locations in underground mines is practically impossible. Drones in underground mines could be used for a variety of health and safety purposes. Surface roughness mapping, rock mass stability analysis, ventilation modeling, hazardous gas detection, and leakage monitoring are some of these applications.

CONCLUSION AND IMPLICATION

Recent studies and commercially developed commercial drones and services in the mining industry were reviewed in this paper. In addition, the mining industry's use of drones for search and rescue missions was discussed. Aside from that, standard remote sensing equipment placed on drones. The mining industry was examined. In surface mining, drone technology is a common tool. In surface mining, drone technology is a common tool. In comparison to typical monitoring methods, it is efficient and low-cost. Ore control, rock discontinuities mapping, 3D mapping of the mine environment, blasting management, post blast rock fragmentation measures, and tailing stability monitoring are just a few of the possibilities for drones in surface mining. Drones with fixed wings and rotary wings are the most widely utilized in the mining industry, for both research and commercial purposes. Drone uses in underground mines are relatively limited, despite major advancements in drone technology. This is owing to problems such as GPS denial, a lack of wireless signal, confined places, dust and gas concentrations, and generally harsh settings. The use of drones in underground mining has been suggested as a feasible option. Encased drones may be a solution to the environmental challenges that exist in underground mines.

SMART CAMPUS CLOUD COMPUTING ARCHITECTURE: A SECURE AND RELIABLE SOLUTION

Mr Mrinal Paliwal*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: mrinalpaliwal.cse@sanskriti.edu.in

ABSTRACT

The new ideas of smart computing and pervasive computing have penetrated many theoretical spaces and given birth to new concepts under the umbrella of smart environment such as smart homes, smart buildings, smart campuses, smart cities, smarter earth, and so on, driven by the implementation of modern technologies such as cloud and the opportunities provided by these to the benefit of people. The Smart Campus is a novel concept in information technology development, combining Cloud Computing, the Internet of Things, and other emerging technologies. This research paper summarizes the findings of our study into the best options for the creation of a smart campus that also ensures data security, with a particular emphasis on data confidentiality. For the cloud security architecture, our solution offers five layers of protection; it provides a high degree of security as well as strong data secrecy - the necessary backbone for a genuinely smart campus development.

KEYWORDS:*Cloud Computing, Cloud Security Architectures, Data Storage Security, Smart Campus, Steganography.*

24. INTRODUCTION

Higher education is heavily influenced by the smart environment idea. It provides ground-breaking challenges in terms of higher standards and creative methods, emphasizing the university's societal role of thought leadership and practical solutions demonstration. As a result, the university campus is an excellent location for creating a smart environment. Although the field literature does not draw a clear line between concepts such as "smart education," "smart university," and "smart campus," it does address multiple aspects of the taxonomy of these concepts in a trans- and inter-disciplinary manner, beginning with needs and benefits and progressing through features, components, technologies, systems, and architecture[1].

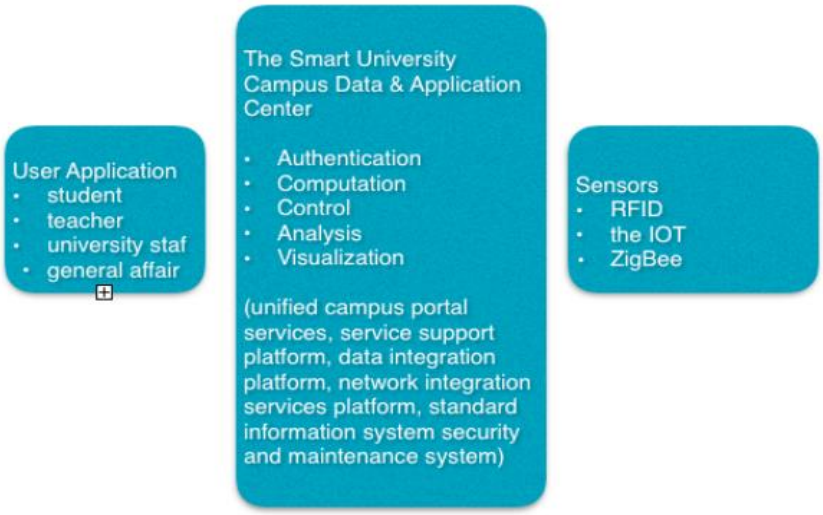

Figure 1: The architecture of the university campus within IoT[2]

The Smart campus, on the other hand, is a novel concept in the field of information technology, combining Cloud Computing, the Internet of Things, and other emerging technologies [3]. Cloud Computing, which also provides supercomputing and storage capacity, allows for a comprehensive integration of resources. The internet of things is the result of a successful integration of sensor networks, the Internet, and mobile communication networks, with the sensory system at its heart.

Figure 1 shows the architecture of a smart campus built on cloud computing and the Internet of Things, which includes unified campus portal services, service support platform, data integration platform, network integration services platform, and standard information system security and maintenance system. The cloud computing platform and its confidentiality and security needs are the subject of this article. The following is a breakdown of the paper's structure. Section 2 discusses Smart Campus Security Issues and Concerns, with an emphasis on the University of Oradea's Smart Campus. The significance of protecting the cloud computing architecture for a Smart Campus is discussed in Section 3. The suggested secured cloud computing architecture for the smart campus is presented in Section 4. It is based on the use of five levels of protection. To improve data secrecy, the top security layer employs steganography. Finally, there is a section that discusses possible enhancements to the suggested solution.

25. DISCUSSION

25.1. Smart Campus Classification and Improvement Approaches:

The concept of smart campus has evolved from a simple engineering digital campus to a hybrid of physical and digital space that includes everything from campus cards, virtual campuses, mobile platforms, datacenters, smart infrastructures, intelligent buildings, sustainable development, and energy efficient operations, among other things, to the intelligence of teaching and research, management, and serendipity. The fast growth of science and technology, such as big data, the Internet of Things, and cloud computing, as well as the formation of a global vision towards sustainability and the United Nations (UN) Sustainable Development Goals, have pushed the idea of smart campus ahead (SDGs).

The difference between "smart campus" and "smart university" has been emphasized from a technical standpoint. Smart campus models are being developed by a growing number of academics and practitioners. Because of the many parallels between university campuses and cities, Pagliaro et al. believe that the smart city concept may be expanded and modified to establish a smart campus. Planning, integration and cooperation, adaptability, and scalability are

the five pillars of their methodical approach [4]. Mattoni et al. suggested a smart campus model based on two aspects: identification of reciprocal effects across smart fields and prioritizing based on a number of variables including production timelines, integration degree, viability, stakeholder opinion, and so on [5]. The smart campus's structure is a hybrid of physical and digital space, according to Liu.

We will consider that the smart campus system combines, using IoT, the physical devices of our digital university with cloud computing and storage in our approach, thinking that the IoT Strategy and Digital Tools may help solve major problems in Higher Education. Figure 2 depicts our proposed smart campus concept. Smart Campus is a cloud computing platform that uses IoT technology to connect isolated systems such as educational management systems, financial management systems, office systems, and facilities management systems. We build an ecosystem by using the Internet of Things, which allows for the integration of data from many devices into a single platform, where analytics can assist produce actionable insights.

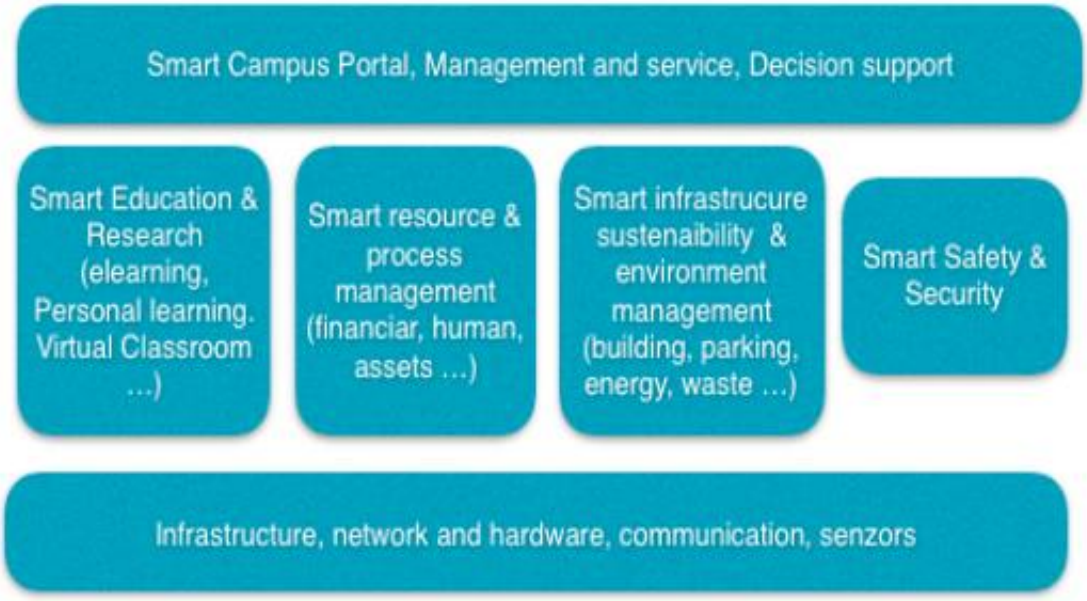

Figure 2: Illustrates the Smart Campus Model [2]

Many intelligent activities, such as social networking holistic e-learning, communication for work collaboration, green and ICT energy efficiency with intelligent sensor management systems, preventive and protective health care, intelligent buildings management with automated security control and surveillance, and visible governance and reporting, waste management, must be considered in the Smart Campus.

25.2. Significance of a Secure Cloud Design for a Smart Campus:

Regardless of the problems addressed, making the campus Wi-Fi enabled is the most critical need for it to be smart. The need for intelligent and ubiquitous devices to activate internet-based device navigation on university campuses is growing. As a result, implementing a BYOD policy for internet surfing via Wi-Fi poses a problem in terms of creating a safe navigation experience [6]. The goal of this article is to create a safe and reliable cloud computing architecture based on the separation of Internet surfing into two areas: Internet Restricted Zone (IRZ) and Internet Public Zone (IPZ).

A unified campus portal services, service support platform, information management platform, network integration services framework, and standard information system security and maintenance system are all part of a smart campus built on cloud computing architecture. Our Smart University Campus design, shown in Fig. 3, will be based on their concept. In our

approach, we assume a 4-layer Unified Portal System, with the Information Gathering Layer as the lowest layer, which is responsible for gathering data in real-time or non-real time.

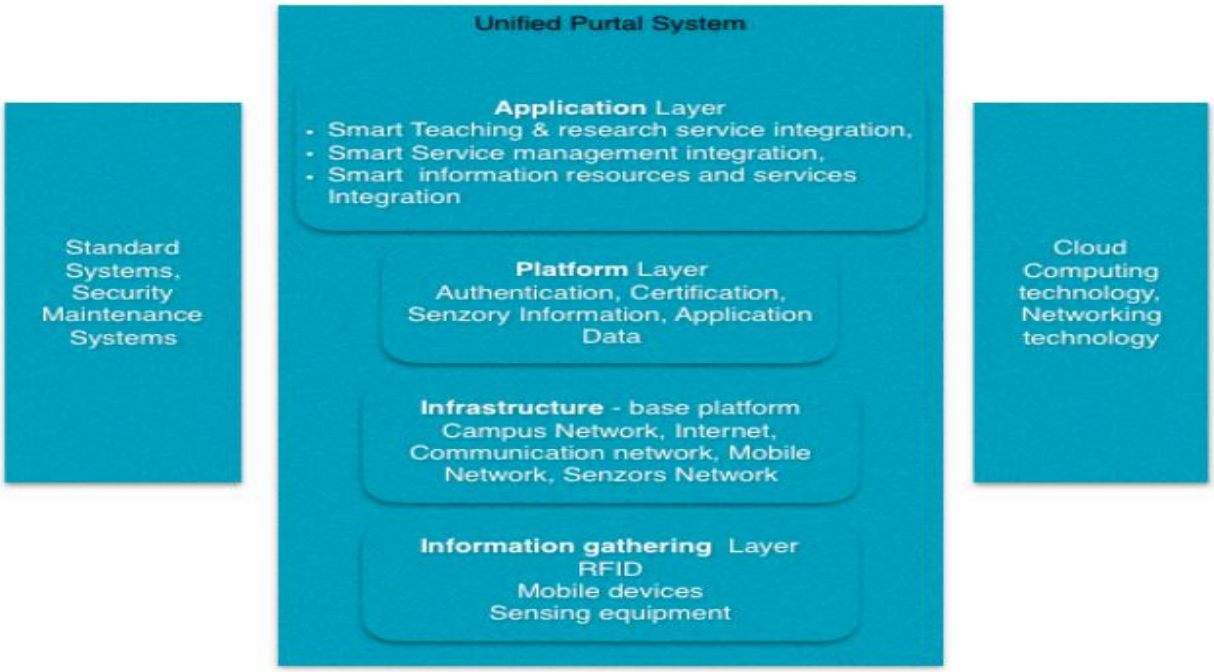

Figure 3: Smart Campus System Architecture

The smart campus, which is built on IoT and cloud computing technologies, raises a slew of problems that need to be addressed. These are linked to: top-level design flaws; the requirement for uniform data standards for RFID labels and sensors; and data protection and security issues associated with cloud computing.

The data security and data confidence for the smart university campus are the main topics of discussion in this article. In this regard, achieving a proper data classification and identifying the secret data whose confidence is critical is a critical step in building a safe, confident smart campus architecture. Our suggested architectural approach will provide an extra layer of protection for this data.

25.3. Secure Cloud Computing Architecture for a Smart Campus:

25.3.1. Cloud Security Architectures:

Cloud Computing (CC) is a valuable business tool since it is an effective method to store and manage databases. CC's services are delivered as a software as a service (SaaS), which has the benefit of being less expensive than traditional computer solutions (the price is offered on a user basis). Furthermore, effective CC usage lowers energy consumption and frees clients from IT installation and maintenance concerns[7]. Cloud users access the cloud through a Cloud Portal, which enables them to choose a service from a catalog, with the cloud management system allocating the appropriate resources via the provisioning service. The optional cloud monitoring and metering system keeps track of cloud use and lets you allocate resources to specific users. The fact that computers are not directly accessible via network connections, but rather by the services they offer, gives the cloud a high level of openness. Users may actually access certain cloud components (application brokers) that distribute requests to specific servers.

As illustrated in Fig. 4, cloud security components are defined, and an architectural solution for cloud computing environments is suggested. Security components and services must be visible and generic in order to maintain the openness of cloud computing.

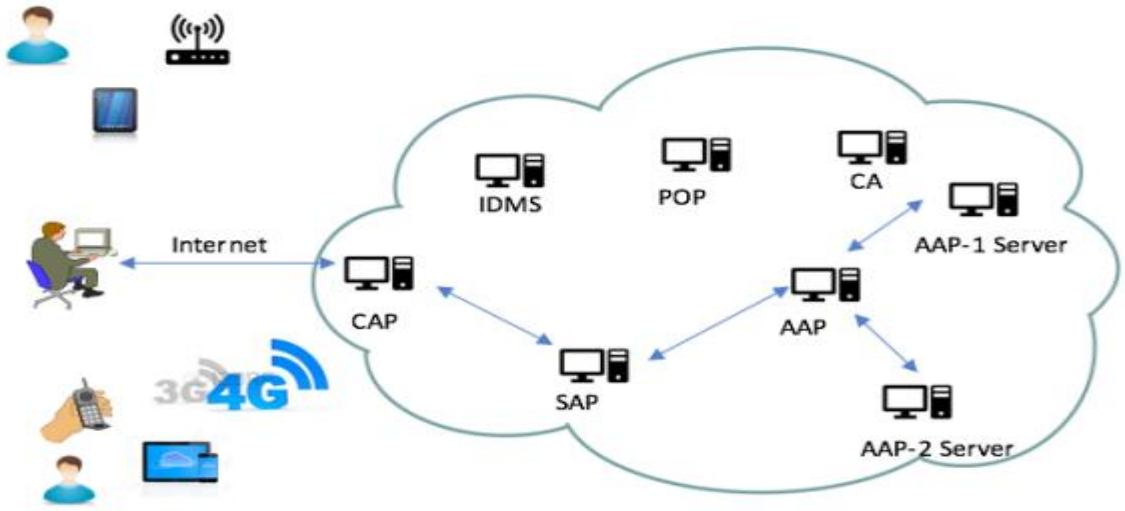

Figure 4: Security Components and Architecture for Cloud Computing [8]**.**

25.3.2. Steganography for Secrecy of Data Stored in the Cloud:

In general, when it comes to cloud computing, there are two main security concerns:

- People are skeptical that service providers would not exploit client data housed on an unknown server.
- When data is put into the server, it is exposed.

Since a result, managing "data-at-rest" in cloud computing is critical, as it must be secured from unwanted users. Today's encryption techniques are employed by storage devices to prevent unwanted access to data; nevertheless, if malevolent users get access to encryption and decryption keys, encryption methods will not offer permitted access.

25.3.3. The 5 Layer Cloud Security Architecture:

Bhadoria et al. developed a four-layer cloud security architecture that protects all three key components of cloud computing: identity, information, and infrastructure [9]. This architecture is finished with a 5th extra layer, as shown in Figure 5 that enhances cloud computing data trust and therefore security for data at rest in the cloud by concealing information in pictures [10].

- Layer 1 is based on a third-party cloud provider's Cloud Identity Access Management (IAM) function gateway. It explains how to use the IAM function. This will be accomplished by integrating provisioning/de-provisioning, authentication, federation, and authorization into web security application services. These online security apps will be utilized as an additional layer of security.
- A firewall is introduced at Layer 2 to improve network security control (allow ports and IP access). This layer protects both the physical infrastructure of the service client and the physical infrastructure of the cloud service.
- Layer 3 improves client data isolation by separating organizations' data and utilizing private VLANs that are set based on access limitations for each customer's virtual machine, based on Access Control Lists.
- For each client, Layer 4 employs virtual demilitarized zone security (DMZ). This virtual zone will limit access to information stored on the private VLAN. CSP will also have a DMZ zone that all customers will be able to access. Data about all consumers will be kept in this zone — without impacting the data of individual customers.

- Security Layer 5 is an additional layer that considers the steganography method. It uses pictures to conceal data stored in the public cloud.

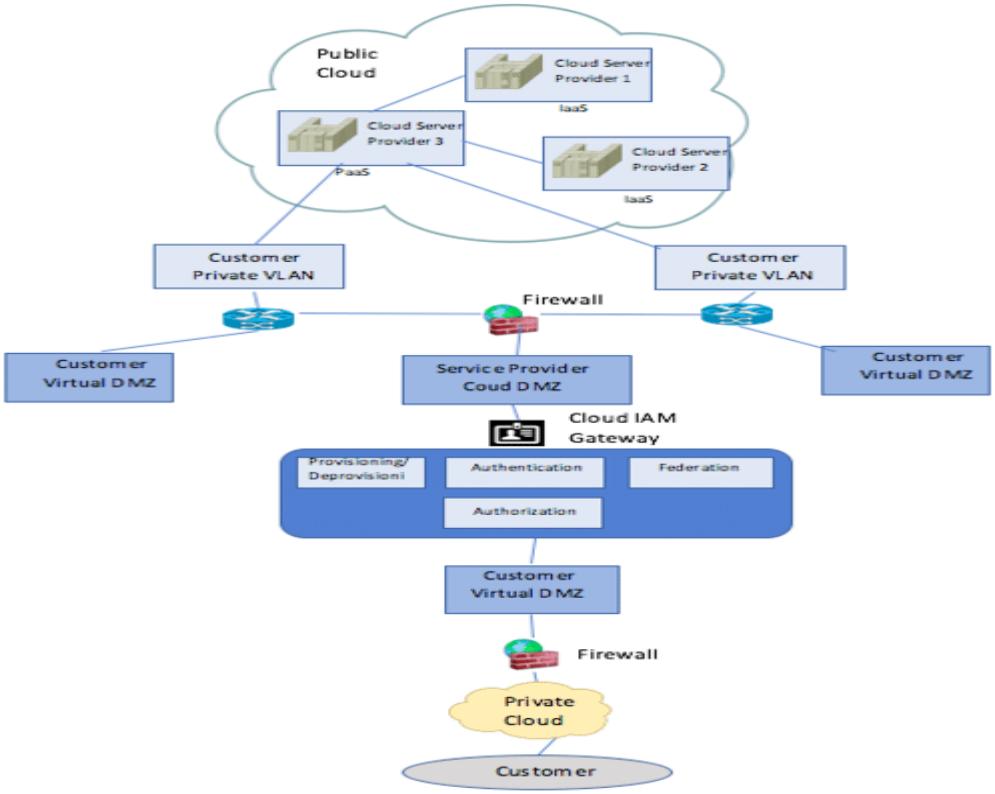

Fig. 5: The 5 Layer CSA Architecture [10]

26. CONCLUSION

Data confidentiality and data protection are significant research directions today, therefore we concentrated our efforts on finding the finest solutions that satisfy the development requirements of smart campus development while also ensuring smart campus data security, with a special emphasis on data secrecy. We suggested a smart campus design that combines the usage of cloud computing and IoT, starting with the establishment of the smart campus model. The paper's main contribution is a secure and confident 5-layer cloud architecture solution that can be used for our proposed Smart Campus System Architecture in order to ensure a high level of security and data confidentiality for the smart campus - the essential backbone for a true smart campus development. The prototype solution is meant to be used in the instance of the University of Oradea's Smart Campus, which has a lot of room for growth.

Our suggested solution is still under development, but it contains basic capabilities as well as support for more sophisticated analyses. The development of new suitable software tools to enhance safe cloud architecture solutions and assist smart campus development will be the focus of future efforts.

A SURVEY OF FOG COMPUTING: PRIVACY AND SECURITY CONSIDERATIONS

Mr. Swapnil Raj*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: swapnil.cse@sanskriti.edu.in

ABSTRACT

Because of the inherent limitations of Internet of Things (IoT) devices, such as limited storage and computing capacity, a new platform is required to handle data effectively. Fog computing is a technique that was developed to bridge the gap between distant data centers and IoT devices. Fog computing offers a number of advantages, including increased security, reduced bandwidth, and lower latency. Because of these advantages, fog is an ideal paradigm for many IoT services in a variety of applications, including linked cars and smart grids. Nonetheless, fog devices, like conventional data centers, are exposed to a variety of security and privacy risks. The authors of this paper address security and privacy concerns in IoT settings and suggest a fog-based method to optimize the dissemination of certificate revocation information across IoT devices for increased security. They also discuss possible research paths for utilizing fog computing to improve security and privacy in IoT settings.

KEYWORDS:*Edge Computing, Fog Computing, Internet Of Things (Iot), Privacy, Security.*

27. INTRODUCTION

The rise of ubiquitously linked smart gadgets is changing the computer landscape. Wearable computing, smart metering, smart home/city, linked cars, and large-scale wireless sensor networks are all contributing to the Internet of Things, which connects and smartens everything (IoT). According to IDC (International Data Corporation), "the Internet of Things will continue to quickly grow the conventional IT industry" in 2015, increasing 14% from 2014 [1]. As we all know, smart gadgets confront a slew of issues relating to computing power, battery life, storage, and bandwidth, all of which impede Quality of Service (QoS) and user experience. Cloud computing is a potential computing paradigm that may provide services to end users in terms of infrastructure, platform, and software, as well as provide applications with elastic resources at cheap cost, to relieve the strain of restricted resources on smart devices.

However, cloud computing is not a "one-size-fits-all" answer. Since IoT applications often need mobility support, geo distribution, position awareness, and low latency, there are still issues to be addressed. Fog computing, also known as edge computing, aims to enable computation at the network's edge, allowing billions of linked devices to benefit from new applications and services

[2]. Set-top boxes, access points, roadside units, cellular base stations, and other fog devices are common. End devices, fog, and cloud create a three-layer hierarchical service delivery architecture that supports online content distribution, augmented reality, and big data analysis. Figure 1 depicts a typical fog/cloud infrastructure conceptual design.

Because fog is considered a non-trivial extension of cloud computing, certain security and privacy problems that arise in cloud computing are expected to have an unavoidable effect on fog computing. If security and privacy concerns are not addressed, fog computing adoption will lag, owing to the fact that 74 percent of IT executives and chief information officers reject cloud computing due to security and privacy concerns. Because fog computing is still in its infancy, little attention has been paid to security and privacy concerns. Because fog computing is suggested in the context of the Internet of Things (IoT) and evolved from cloud computing, fog computing inherits cloud security and privacy concerns. While certain problems may be handled using current methods, others face new hurdles as a result of fog computing's unique features, such as heterogeneity in fog nodes and fog networks, the need for mobility support, large scale geo-distributed nodes, location-awareness, and low latency.

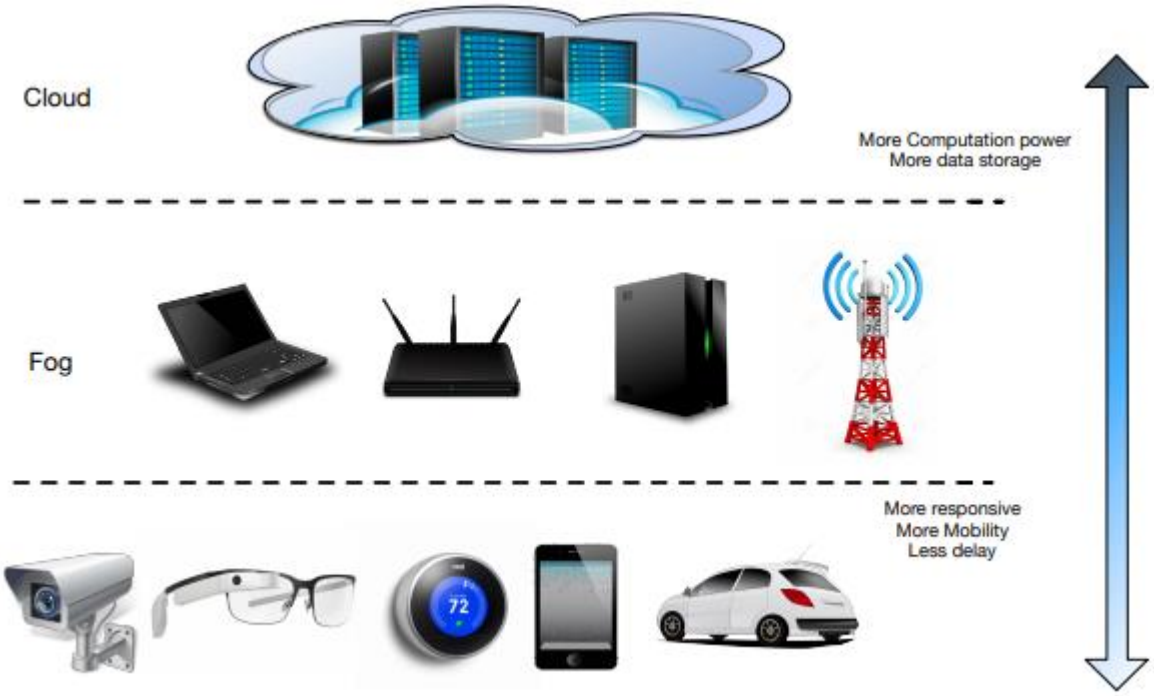

Figure 1: An example of fog/cloud architecture [3]

We will address various security and privacy concerns in fog computing in this article by analyzing current fog computing work as well as related work in underlying areas to identify security and privacy issues.

27.1. Fog Computing Overview:

This section provides a high-level overview of fog computing. We prefer not to address cloud computing or mobile cloud computing, and anyone interested in learning more may consult previous surveys.

27.1.1. Definition:

Fog computing, as a new computer paradigm, is still a nascent idea in the community. Fog computing is defined in this article as an extension of cloud computing to the network's edge, and it is a highly virtualized resource pool that offers compute, storage, and networking services

to local end users. Fog computing is a scenario in which a large number of heterogeneous (wireless and sometimes self-reliant) pervasive and decentralized devices communicate and potentially collaborate among themselves and with the network to perform storage and processing tasks without the involvement of third parties [4]. These responsibilities may include supporting fundamental network operations as well as developing new services and apps for use in a sandboxed environment. Users that lease a portion of their devices to host these services are rewarded. Fog computing is no longer a buzzword, despite the fact that its meanings are still disputed.

27.1.2. Characterization:

Fog computing benefits from its edge position since it can serve applications with low latency needs (e.g. gaming, augmented reality, real-time video stream processing). This edge location may also give extensive network context information, such as local network state, traffic statistics, and client status, which fog applications can utilize to enable context-aware optimization. Another intriguing feature is position awareness; the geo-distributed fog node can not only infer its own location, but it can also monitor end user devices to enable mobility, which may be a game changer for location-based services and applications. Interactions between fog and fog, fog and cloud, and fog and cloud are also essential since fog may readily get local overview but worldwide coverage can only be obtained at a higher layer.

28. DISCUSSION

28.1. Security and Privacy Issues:

We acknowledge that while building a fog computing system, security and privacy should be considered at every layer. “What is new about fog computing security and privacy?” we ask ourselves. Because of the features of fog computing, we may need to do further work in the future to solve those issues.

28.1.1. Trust and Authentication:

Data centers are often owned by cloud service providers in cloud computing deployments. However, owing to various deployment options, fog service providers may be distinct parties: 1) Internet service providers or wireless carriers with control of home gateways or cellular base stations may create fog using their current infrastructures; 2) Cloud service providers that wish to extend their cloud services to the network's edge can build fog infrastructures as well. 3) End users that possess a local private cloud and want to lower their ownership costs would want to convert it to fog and lease excess resources on the local private cloud. Fog's trust condition is complicated by this flexibility.

- **Trust Model:**

In eCommerce, peer-to-peer (P2P), user reviews, and online social networks, the reputation-based trust model has shown to be effective. Damiani et al. developed a robust reputation system for resource selection in P2P networks, which uses a distributed polling method to evaluate a resource's trustworthiness before downloading it [5]. We may need to address problems such as 1) how to establish permanent, unique, and distinct identity, 2) how to handle deliberate and unintentional misbehavior, and 3) how to perform reputation punishment and redemption while building a fog computing reputation-based reputation system. There are other trusting models based on specific hardware that may offer trust utility in fog computing applications, such as Secure Element (SE), Trusted Execution Environment (TEE), or Trusted Platform Module (TPM).

- **Rogue Fog Node:**

A rogue fog node is a fog device or fog instance that masquerades as genuine in order to get end users to connect to it [6]. A fog administrator, for example, may be allowed to manage fog instances but may instead create a rogue fog instance in the event of an insider assault. The possibility of a man-in-the-middle attack in fog computing has been proven, and the gateway should either be hacked or replaced with a fake one before the assault. Once linked, the attacker may simply modify incoming and outgoing requests from end users or the cloud, surreptitiously gather or tamper with user data, and launch further assaults. The presence of a false fog node poses a significant risk to user data security and privacy. This is a difficult issue to solve in fog computing for a variety of reasons. 1) Different trust management methods are required in complicated trust situations; 2) maintaining a blacklist of rogue nodes is difficult due to the dynamic creation and deletion of virtual machine instances. Han et al. presented a measurement-based technique for preventing a client from connecting to a rogue access point (AP). To identify rogue APs at the client side, they utilize the round-trip duration between end users and the DNS server.

- **Authentication:**

Because front fog nodes provide services to massive-scale end users, authentication is a critical problem for fog computing security. The primary security problem of fog computing, according to Stojmenovic et al., is authentication at various levels of fog nodes [7]. Traditional PKI-based authentication is inefficient and inefficiently scalable. Balfanz et al. presented a low-cost, secure, and user-friendly solution to the authentication issue in local ad-hoc wireless networks, which relies on a physical touch for pre-authentication in a location-limited channel [8]. In the case of cloudlets, NFC may also be utilized to ease the authentication process. With the rise of biometric security in mobile computing and cloud computing, such as biometric verification, face authorization, touch-based or keystroke-based authorization, and so on, biometric based authentication in fog computing will be advantageous.

28.1.2. Network Security:

Because wireless is so prevalent in fog networking, wireless network security is a major issue. Jamming attacks, sniffer attacks, and other types of assaults are examples. These threats can be handled in the wireless network research area, which is beyond the scope of this study [9]. Normally, we must trust the settings created manually by a network administrator and separate network administration traffic from normal data traffic in a network. Fog nodes, on the other hand, are placed at the Internet's edge, putting a significant strain on network administration. Consider the expense of running large scale cloud servers that are dispersed throughout the network edge with no simple access for maintenance. In many areas of fog computing, SDN may simplify installation and administration while also increasing network scalability and lowering costs. We also suggest that using SDN in fog computing will provide new problems and possibilities for fog networking security.

28.1.3. Secure Data Storage:

User data is outsourced to fog nodes, and users' control over data is given over to fog nodes, posing the same security risks as cloud computing. First, data integrity is difficult to guarantee since outsourced data may be lost or improperly changed. Second, the submitted data may be utilized for other purposes by unauthorized parties.

To safeguard data from these risks, an auditable data storage service has been suggested in the context of cloud computing. To guarantee integrity, secrecy, and verifiability for cloud storage systems, techniques such as homomorphic encryption and searchable encryption are used to enable a client to verify its data stored on untrusted servers. Want et al. suggested privacy-preserving public auditing for cloud data that depends on a third-party auditor (TPA), utilizing a

homomorphic authenticator and a random mask method to preserve privacy from TPA. Prior storage systems dealt with data corruption detection and repair using erasure codes or network coding, while Cao et al. developed a method utilizing LT code, which offers reduced storage cost, considerably quicker data retrieval, and similar communication cost. Yang et al. have given a fair summary of current work in cloud computing data storage auditing services.

28.1.4. Secure and Private Data Computation:

Another major problem in fog computing is how to outsource computation to fog nodes while keeping it safe and private.

- **Verifiable Computing:**

Verifiable computing allows a computer equipment to outsource the calculation of a function to other, potentially untrustworthy servers while still ensuring that the results are verifiable. The other servers evaluate the function and provide the result, along with a verification that the function was computed properly. The fog user should be able to verify the accuracy of the computation offloaded to the fog node to instill confidence in the computation offloaded to the fog node.

- **Data Search:**

To preserve data privacy, end users' sensitive data must be encrypted before being sent to the fog node, making effective data utilization services difficult. Keyword search, i.e. keyword search among encrypted data files, is one of the most essential services. Researchers have devised a number of searchable encryption methods that enable a user to do secure keyword searches over encrypted material without having to decode it. The authors presented the first ever search method for encrypted data, which includes proven secrecy for encryption, query isolation, controlled searching, and concealed query support.

28.1.5. Privacy:

When end users utilize services like cloud computing, wireless networks, and IoT, the leakage of private information such as data, location, and use is getting attention. Because fog nodes are closer to end users and may gather more sensitive data than the distant cloud on the core network, maintaining such privacy in fog computing poses additional difficulties. In a variety of situations, such as the cloud, smart grid, wireless network, and online social network, privacy-preserving methods have been suggested.

- **Data Privacy:**

Privacy-preserving algorithms can operate in the fog network between the fog and the cloud, but they are typically resource prohibitive at the end devices. Sensors and end devices produce sensitive data, which is collected by fog nodes at the edge. At the local gateways, techniques like homomorphic encryption may be used to provide privacy-preserving aggregation without decryption. In the case of statistical inquiries, differential privacy may be used to guarantee that the privacy of an arbitrary single item in the data set is not revealed.

- **Usage Privacy:**

Another privacy concern is the manner in which a fog client use fog services. For example, with a smart grid, the reading of a smart meter would reveal a lot of information about a household, such as when no one is at home and when the TV is switched on, which is completely in violation of the user's privacy. Despite the fact that privacy-preserving methods have been suggested for smart metering, they cannot be directly used to fog computing owing to the absence of a trusted third party (i.e., a smart meter in a smart grid) or a counterpart device such as a battery. The fog node, which may readily gather end-user use data. One naïve approach is

for the fog client to generate fake jobs and offload them to several fog nodes, thus concealing its actual activities behind the dummy ones. This approach, on the other hand, will raise the fog client's payment as well as waste resources and energy. Another option is to devise a clever method of dividing the program to ensure that offloaded resource usages do not reveal personal information.

- **Location Privacy:**

The term "location privacy" in fog computing refers to the secrecy of fog clients' locations. Because a fog client often offloads its duties to the closest fog node, the fog node to which the tasks are offloaded may deduce that the fog client is close by and further away from other nodes. In addition, if a fog client uses several fog services at different places, it may reveal its route trajectory to the fog nodes if the fog nodes cooperate. As long as a fog client is connected to a person or an essential item, the person's or object's location privacy is jeopardized.

If a fog client always picks the closest fog server, the fog node may be certain that the fog client using its computational resources is close by. The only option to keep location privacy is to use identity obfuscation, which means that even if a fog client is close, the fog node cannot identify the fog client. Identity obfuscation may be accomplished in a variety of ways; for example, the authors employ a trusted third party to create false ID for each end user. In reality, a fog client does not always select the closest fog node, but instead chooses one of the fog nodes it can reach based on latency, reputation, load balance, and other factors. In this scenario, the fog node can only estimate the fog client's position but not pinpoint it. When a fog client uses computational resources from several fog nodes in an area, however, its location may be reduced to a tiny zone since it must be near the intersection of the numerous fog node coverages.

28.1.6. Access Control:

Access control has shown to be a dependable technique for ensuring system security while also protecting user privacy. Access control in the traditional sense is typically handled in the same trust domain. Because of the outsourced nature of cloud computing, access control is often handled cryptographically for outsourced data. In terms of key management, a symmetric key-based approach is not scalable. To accomplish fine-grained access control, many public key based methods have been suggested. Yu et al. presented an attribute-based encryption-based fine-grained data access control system (ABE). In fog computing, it will be difficult to build access control that spans client-fog-cloud while still meeting design objectives and resource limitations.

28.1.7. Intrusion Detection:

Intrusion detection techniques are widely used in cloud systems to mitigate attacks such as insider attacks, flooding attacks, port scanning, and attacks on virtual machines and hypervisors, as well as in smart grid systems to monitor power meter measurements and detect abnormal measurements that may have been compromised by attackers [10]. By monitoring and analyzing log files, access control rules, and user login information, IDS may be implemented on the fog node system side to identify intrusive activity in fog computing. They may also be used on the fog network to identify malicious assaults like denial-of-service (DoS), port scanning, and other types of attacks. It opens up new avenues for research into how fog computing may assist with intrusion detection on both the client and centralized cloud sides. A cloudlet mesh-based security architecture has been described by an author that can detect intrusion to a distant cloud while also protecting communication between mobile devices, cloudlets, and the cloud. Implementing

intrusion detection in geo-distributed, large-scale, high-mobility fog computing environments to satisfy the low-latency requirement is also a problem.

29. CONCLUSION

The Internet of Things (IoT) is a rapidly expanding field of study. However, owing to the heterogeneous nature of the linked devices, it still faces many difficulties in terms of implementing access control systems. Because access control is so important, the bare minimum of privileges must be given to ensure that the maintainer cannot utilize all permitted rights during maintenance, as is the case with RBAC and ABAC. Traditional access control schemes need extensive modification and adaption. For this, a publicly accessible capability-based access system for access capabilities and revocation services is being used. Because of the pervasive nature of IoT networks and devices, centralized design has been used to safeguard smart services and resources in recent years. Authentication and authorization duties are handled by back-end servers in this scenario. Traditional access control mechanisms do not provide end-to-end security. As a result, central architecture in the IoT cannot offer scalability for smart items.

This article looks at various security and privacy concerns in the context of fog computing, which is a novel computing paradigm for providing elastic resources to nearby end users at the network's edge. We discuss security issues like secure data storage, secure computation, and network security in this paper. We also discuss data privacy, use privacy, and location privacy, all of which may need fresh thinking in order to adapt to new problems and changes.

A COMPREHENSIVE STUDY OF CLOUD COMPUTING SECURITY

Ms Anuska Sharma*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: anushka@sanskriti.edu.in

ABSTRACT

According to a study, Information Technology (IT) security spending had risen to 79.1 percent in 2015, representing an annual growth of more than 10%. According to the International Data Corporation (IDC), 74.6 percent of corporate clients rated security as a significant issue in 2011. This document compiles a number of peer-reviewed papers on cloud computing security risks and countermeasures. Our study aims to better understand cloud components, security problems, and dangers, as well as developing solutions that may help reduce cloud vulnerabilities. It is a well-known truth that the cloud has been a viable hosting platform since 2008; nevertheless, the view of cloud security is that it requires substantial changes in order to achieve greater rates of adaptation at the corporate scale. Many of the problems facing cloud computing, as highlighted by another study, need to be addressed immediately. The industry has made considerable progress in combating cloud computing risks, but there is still work to be done to reach the level of maturity that conventional or on-premise hosting has.

KEYWORDS: *Cloud Security, Cloud Computing, Security Threats, Security In Cloud.*

30. INTRODUCTION

Cloud computing is being used by a growing number of users, ranging from businesses to individuals. According to a Right Scale study, the typical user uses at least four cloud-based apps and is considering another four at any one moment[1]. According to the study, 41% of business organizations use public clouds to handle substantial workload. With so much of our burden going to the cloud, cloud computing security is becoming more of a concern. This estimate is backed up by a Forbes study from 2017, which claims that although 80 percent of all IT expenditures would be dedicated to cloud solutions in the next 15 months, 49 percent of companies are postponing cloud implementation owing to security skills gaps and concerns[2]. Lack of competent resources, lack of maturity, competing best practices, and complicated business frameworks, to mention a few, seem to be part of the issue. Cloud adoption has reached a tipping point, and it is anticipated that more workloads will migrate from conventional local storage to cloud, not only from ordinary Internet users, but from most, if not all, business organizations. While there are many issues that must be identified, analyzed, and addressed, this

article tries to review cloud computing security and reports on different elements of security vulnerabilities and remedies. The following are some questions that need immediate answers[3]:

- Data Location
- Data Protection and Recovery Support
- Data Segregation
- Investigative Support
- Long-term Viability
- Privileged User Access Management
- Regulatory Compliance

These concerns, as well as other potential hazards, should be evaluated and addressed. The following are some examples of possible assessments[4], [5]:

- Application migration and performance risk
- Extended supply chain risks
- Organization capability and maturity
- People risks
- Policy risks
- Process risks
- Technology & data risks

This paper brings together a number of studies that look at the dangers, vulnerabilities, and possible controls associated with cloud computing. It also includes details on the most popular cloud architectures and frameworks. Furthermore, the paper suggests possible future research topics in cloud computing security. The following is how the rest of the paper is organized: Section 2 delves into the cloud architecture, as well as the security implications of various deployment and delivery methods, as well as general vulnerabilities, attacks, and threats. It also contains information on countermeasures and controls. Finally, part 3 brings the study to a close by outlining possible future paths.

31. DISCUSSION

31.1. Cloud Architecture:

It's crucial to grasp the cloud concept and architecture before diving into security concerns. Cloud computing, according to Sharma and Trivedi, is a collection of resources that can be scaled up and down on demand. It's a self-service approach that requires little to no contact with the service provider via the Internet. With creative, technological, and pricing possibilities, cloud allows new methods of providing goods and services.

There are five main variables that affect and are influenced by cloud computing, as shown in Table 1 from NIST's Cloud Computing Reference Architecture, as well as its security implications. The danger and risk perceptions of cloud consumers and providers are the subject of this study.

TABLE 1: FACTORS IN NIST CLOUD COMPUTING REFERENCE ARCHITECTURE[6], [7]

Actor	Definition
Cloud Consumer	A person or Organisation that maintains a business relationship with, and uses service from, *Cloud Provider*
Cloud Provider	A person, organisation, or entity responsible for making a service available to interested parties
Cloud Auditor	A party that can conduct independent assessment of cloud services, information system operations, performance, and security of the cloud implementation
Cloud Broker	An Entity that manages the use, performance, and delivery of cloud services and negotiates relationship between *Cloud providers* and *Cloud Consumers*
Cloud Carrier	An intermediary that provides connectivity and transport of cloud services from *Cloud Providers* to *Cloud Consumers*

Figure 1 depicts a full cloud computing reference architecture. It's worth noting that the diagram depicts an end-to-end reference design that covers all seven levels of the Open Systems Interconnection (OSI) model, as well as business, commercial, and governance considerations. Cloud computing, as is clear, is a complete and sophisticated solution with many weaknesses.

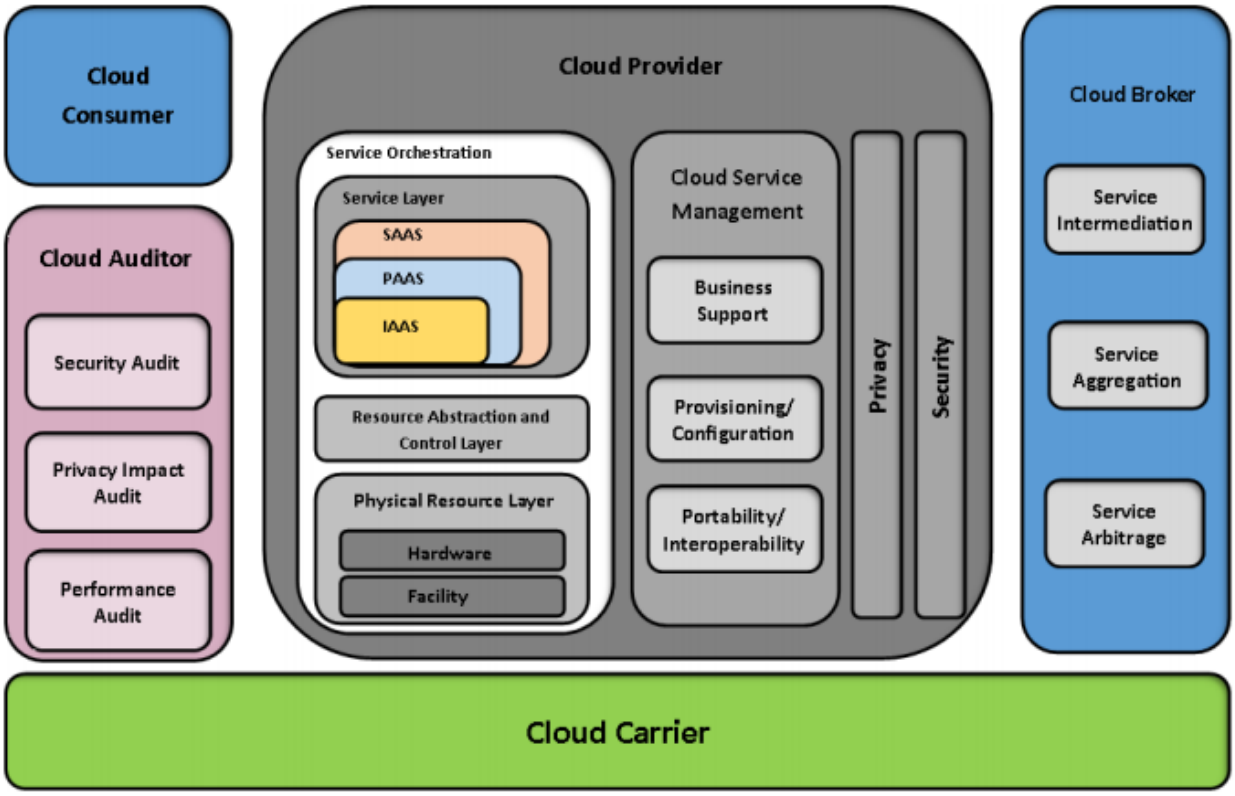

Figure 1: NIST Cloud Computing Reference Architecture[8]

31.1.1. Advantages of Cloud:

There are some unique advantages to cloud computing and some of them are listed below[9].

a. Almost immediate access to the resources.

b. Cost of entry for all organizations including small firms.

c. Implement and/or offer new class of application and delivery services.

d. Reduction in IT barriers to innovation.

e. Easy to scale the services.

31.2. Security Implications based on Deployment and Delivery Model:

The two most important aspects that determine the level of vulnerability in a cloud-computing platform is the choice of deployment and delivery model. According to NIST, there are three

deployment and three delivery models that are considered as industry standards. Each of these three deployment and delivery models have unique security implications. The following sub-sections briefly discuss each of these models and their security implications:

31.2.1. Cloud Deployment Model:

The three most common types of cloud deployment models are Private Cloud, Public Cloud, and Hybrid Cloud as illustrated in Table 2[10].

TABLE 2: ILLUSTRATES THE CLOUD DEPLOYMENT MODEL[10]**.**

Deployment Type	Description	Implications	Challenges
Private Cloud	The cloud service provider pools scalable resources and virtual applications and makes them accessible to cloud customers in a private cloud. The resources are allocated to a single or a group of companies under this deployment paradigm, and the intranet capability is regarded as such. The invoicing is typically done on a subscription basis, with the cloud user committing to a minimum amount of time.	Positive security implications are quite substantial, and the organization has considerable control over the deployment architecture, procedures, and tools.	High installation and administration costs, expertise requirements, and vulnerability management are among security difficulties. Cost and return on investment are important considerations in this deployment strategy, and security implementation is typically dependent on risk assessment, thus security coverage is not complete.

Public Cloud	Resources are dynamically committed on a fine-grained, self-service basis in a public cloud through the Internet or a portal10. The majority of billing is dependent on use and is paid on a pay-per-use basis.	Because of the high number of cloud users and transaction volumes involved, there are positive security implications. Because of its install once and use many times approach, which substantially lowers the cost of security implementation for the customer, the cloud service provider often has a sophisticated and layered security system that may possibly offer a high level of protection.	Because the resources are not dedicated but shared among many cloud users, security risks are increased. This not only adds to the effort of ensuring that all apps and data accessible on the public cloud are secure, but it also requires managing a plethora of external factors such as legal, data protection, and so on.
Hybrid Cloud	A hybrid cloud is a deployment strategy in which a private cloud is connected to one or more external cloud services and controlled from a central location. It offers cloud users with a versatile and fit-for-purpose solution that is relatively simple to use. In terms of billing and advertisements, hybrid clouds have a greater level of complexity.	Positive security implications include the ability to custom-build protection for identified weaknesses, threats, and dangers. As a result, it is both cost-effective and targeted.	Because the deployment strategy is complicated, with a heterogeneous environment, various orchestration, and automation technologies, security concerns are quite significant. This will add to the administrative burden, and any oversight will expose the company to considerable risk.

31.2.2. Cloud Delivery Model:

Platform as a Service (PaaS), Infrastructure as a Service (IaaS), and Software as a Service (SaaS) are the three cloud delivery models suggested by NIST and used by the industry

TABLE 3: CLOUD DELIVERY MODEL[11]

Delivery Type	Description	Risk and responsibility
Infrastructure as a Service (IaaS)	Infrastructure as a Service (IaaS) is a multi-tenant cloud layer in which the cloud service provider only shares dedicated resources with contractual customers for a pay-per-use charge.	This is a fantastic approach in which the cloud user creates the application without having to worry about the infrastructure. The cloud service provider and the cloud customer share security responsibilities equally. The risk is segmented and stacked in this approach. It's also a risk-sharing model.
Platform as a Service (PaaS)	Platform as a Service (PaaS) is a common delivery model in which the cloud provider provides both the operating system and the development stack. Database and application management, as well as development services, are typical practices for providers under this paradigm. PaaS, like IaaS, is a pay-per-use model.	This is a suitable paradigm, in which the cloud consumer delivers application knowledge, as well as licenses, data, and resources, to the platform shell and consumes it. Consumers that lack infrastructure expertise or wish to save money on the significant capital expenditure (capex) needed to construct infrastructure adopt this approach. The security duty shifts more on the cloud provider in this delivery paradigm. This is a shared risk paradigm, similar to IaaS, except the service provider carries a greater risk than the customer since the provider supports more levels.
Software as a Service (SaaS)	In a Software as a Service approach, the cloud provider hosts the whole application stack and offers end-to-end resources, such as licensing, application, and networking. In a web service or software-oriented architecture, the cloud consumer usually provides data and business processes to consume the services.	This approach is particularly useful when the cloud user lacks the required expertise, time, or resources to build up and maintain an application ecosystem. This approach also offers the greatest commercial advantage while requiring no upfront capital expenditure. The cloud provider is primarily responsible for security. Client-side vulnerabilities are mostly the responsibility of the customer. The service provider is the one who carries the greatest risk in this arrangement.

31.3. General Vulnerabilities, Threats, and Attacks in Cloud:

Cloud computing, like other areas of IT, has a variety of security concerns that must be addressed. These dangers include policy and organizational dangers, technological dangers, and legal and other dangers.

31.3.1. Vulnerabilities and open issues:

Cloud is a collection of technology, processes, people, and business models. Cloud, like any other technology, process, person, or business creation, has flaws. The following are some of the cloud's vulnerabilities. The following are some of the outstanding problems and dangers that need immediate attention:

- **Data Breach:**

The danger of an accidental, malicious, or deliberate data breach is significant when data security moves from the cloud customer to the cloud service provider.

- **Shared Technology vulnerabilities:**

Increased resource leverage provides attackers with a single point of attack, which may inflict harm that is out of proportion to its significance. A hypervisor or cloud orchestration are examples of sharing technology.

- **Account of Service traffic hijacking:**

Access to the cloud through the Internet is one of its greatest benefits, but it also comes with the danger of account breach. Losing access to a privileged account may result in service interruption.

- **Malicious Insider***:*

In a cloud site, a motivated insider may discover additional methods to attack and hide the trail.

- **Denial of Service (DoS):**

Any denial of service assault on the cloud provider has the potential to disrupt all of the tenets.

- **Internet Protocol:**

IP spoofing, ARP spoofing, and DNS poisoning are just a few of the IP vulnerabilities that may be exploited.

- **API & Browser Vulnerabilities:**

When combined with social engineering or browser-based assaults, any vulnerability in a cloud provider's API or interface presents a major danger; the damage may be considerable.

- **Injection Vulnerabilities:**

Vulnerabilities in the administration layer, such as SQL injection flaws, OS injection, and LDAP injection, may create significant problems for many cloud users.

- **Changes to Business Model:**

A cloud consumer's business model may be significantly altered by cloud computing. The IT department, as well as the company, must adapt or risk being exposed to danger.

- **Malicious Insider:**

A hostile insider is always a threat, but a malicious insider at a cloud provider may do substantial harm to a large number of customers.

- **Abusive Use:**

Certain cloud computing capabilities, such as the usage of a trial period of use to conduct zombie or DDoS assaults, may be used for malicious offensive objectives.

- **Availability:**

The likelihood that a system will perform as expected and on time.

31.3.2. Attack Vectors:

Network, hypervisor, and hardware are the three main attack vectors, according to a recent study. External, internal, and cloud provider or insider assaults are linked to these vectors, accordingly.

32. CONCLUSION

Cloud computing security is developing in lockstep with dangers, which are frequently identified too late to avoid disasters. Cloud computing poses a unique and serious danger to all players owing to its disruptive nature, complicated design, and leveraged resources. Understanding the risk and properly mitigating it is important for all stakeholders and actors. To properly minimize the risk, security must be integrated into every tier of a cloud-computing platform by integrating best practices and new technology. Consumers, providers, brokers, carriers, auditors, and everyone else in the cloud must take the required measures against hazards in order to properly protect the cloud computing platform, or face substantial and sometimes business-critical risk. Security engineering offers best practices, methodologies, and techniques for creating systems and services that are designed for security, sustainability, and resilience, according to a recent study. It's critical to continue this study so that best practices may be applied to additional applications and use cases. Further study in the systems development life cycle (SDLC) for cloud customers is also required in order to integrate different development and technological advancement models, as well as container systems like Docker, to enhance security at a basic level. Furthermore, there is relatively little study on the effect of training and personnel on security. Understanding the difficulties, needs, and effects of good security training for customers and other providers may be done.

ABSTRACT

The results of the vast majority of studies of HDV infection indicate a high incidence of LC as an outcome of the disease with rapid development of liver decompensation. Against the background of rapid progress in the treatment of hepatitis C, the role of the insufficiently studied and difficult to treat HDV infection is currently increasing. The use of interferon preparations does not guarantee a cure in the majority of patients with delta infection, does not provide stable elimination of the virus, and gives many side effects.The presented methodological recommendations developed on the basis of the results of studies carried out in the clinical base of the RSSPMCEMIPD, showed that the administration of nucleoside analogs to patients with HDV infection significantly reduced the concentration of HBV DNA in the liver biopsy, which indicates a decrease in the risk of cytolysis in liver cells.

KEYWORDS: *HDV Infection, HBV DNA, Replication, Liver Biopsy, PCR, Nucleoside Analogs.*

INTRODUCTION

Until today, many aspects of the pathogenesis of hepatitis delta remain unclear. The reasons for such an aggressive persistence of the virus and the role of the HDV virus in suppressing HBV virus replication in the liver cell are not fully understood. Thus, the study of molecular interactions between HDV and HBV viruses remains relevant.

Coinfection and superinfection lead to suppression of HBV replication in both patients and animals and cell models. The observation that HDV can suppress HBV in a coinfected or superinfected setting has also been reported in several retrospective studies (1,2,6,7,9,10).

In a clinical study, Jardi et al. analyzed HBV / HDV coinfection, mixed HBV / HCV / HDV infection, as well as patients with HBV and HCV monoinfection. The authors found that HDV

appears to suppress both HBV and HCV viremia, although HCV replication is reduced to a greater extent than HBV (5).Similar data are given by Heidrich et al. The results of the authors' studies showed that HDV infection suppressed the replication of both HBV and HCV. At the same time, the levels of HBV DNA and HCV RNA did not affect HDV replication in the patient group, the mean HBsAg levels did not differ significantly in patients with HBV monoinfection and with HBV / HDV coinfection (4). Eyster et al. and Mathurin et al. also supported these observations, found that HDV dominates HCV in patients with triple infection, since HCV serum RNA and HBV replication markers were not detected in most patients (3).

To investigate the interaction of HBV and HDV during coinfection, Schaper et al. published interesting data. In 25 patients with chronic HBV / HDV infection, the replicative activities of HBV and HDV were assessed over 8 years. Seven different replication profiles were observed in these patients. In 20% of co-infected patients, they showed persistent HDV activity in the absence of HBV activity; 12% showed persistent activity of both viruses, 12% showed persistent HBV activity in the absence of HDV replication. Of the remaining 56% of patients, 24% showed fluctuating activity for both viruses, and 32% for one of the two viruses. But in most of the observed patients (60%), HDV was dominant (8).

The clinical guidelines of the European Association for the Study of Liver Diseases indicate that the use of nucleoside analogs (AN) does not interfere with HDV replication and associated disease. AH therapy is recommended for patients with HB DNA levels above 2000 IU / ml, patients with decompensated liver disease with detectable HBV DNA levels in HDV infection.

Considering the availability of numerous data and the variety of research results, we determined the goal: to determine the presence of HBV DNA in liver biopsies in patients with CVHB and D with negative PCR for HBV DNA in blood plasma, as well as to assess the feasibility of antiviral AN therapy in this category of patients.

The study was carried out in 32 patients who applied for hospitalization at the NIIEMIZ clinic with a diagnosis of "Chronic viral hepatitis B with a Delta agent". The criterion for the selection of patients with CVHD was the absence of HBV DNA in the blood plasma. The quantitative levels of HDV RNA in the blood were high and the average level was 7658710 copies / ml. To determine the presence and amount of HBV DNA in hepatocytes, all patients underwent liver biopsy. The amount of HBV DNA in the biopsy was determined by PCR. It should be noted that out of 32 examined patients 18 (56.2%) took AN therapy: tenofovir disoproxil fumarate 300 mg / day, 14 (43.8%) did not take nucleoside analogs.

The patients were between 19 and 50 years old and their average age was 35.1 years. There were 23 (71.9%) men and 9 (28.1%) women. Of 32 patients, 13 (40.6%) had Class A LC and 19 (59.4%) had a chronic liver process without LC. Patients with enzymatic activity and with class B, C liver cirrhosis were not included in the study, due to possible complications during biopsy.

We have studied laboratory manifestations in patients with HDV infection. Average levels of biochemical parameters in patients with HDV infection (n = 32) are presented in Table 1.

TABLE 1AVERAGE INDICATOR OF BIOCHEMICAL STUDIES

BIOCHEMICAL INDICATORS IN BLOOD	NORM	PATIENTS WITH HDV INFECTION (n=32)
ALAT, MMOL / L	BEFORE 0,68	0,74
ASAT, MMOL / L	BEFORE 0,45	0,34
TOTAL BILIRUBIN, MCMOL / L		21,3
TOTAL PROTEIN, G / L	64-83	62,3
GLUCOSE		4,1

In the group of patients (n = 32), the mean ALT levels were 0.74 mmol / L, AST 0.34 mmol / L, total bilirubin 21.3 μmol / L, which indicates the absence of cytolytic syndrome. In the group of patients, the level of total protein was 62.3 g / l, which indicates a slight decrease in the protein-synthetic function of the liver.

So, in all examined patients (n = 32), the PCR study for the presence of HBV DNA in blood plasma, the results showed the absence of HBV virus DNA, which is consistent with the data of other researchers (1,2, 12,17,18,22). Liver biopsy examination for HBV DNA, these results were different. In all examined patients, it was found that HBV DNA was detected at a sufficiently high level in the liver biopsy (the average level was 61464 copies / ml). In 9 (28.2%) patients, the HBV DNA level varied 105 degrees, the average HBV DNA was 188,000 copies / ml, in 8 (25%) patients the HBV DNA level was 104 degrees, the average HBV DNA was 26,566 copies / ml and in 15 (46.8%) patients, HBV DNA varied 103, the average HBV DNA was 3640 copies / ml, which indicates intensive replication of HBV DNA in hepatocytes in the absence of HBV DNA in blood plasma in these patients (Fig. 1).

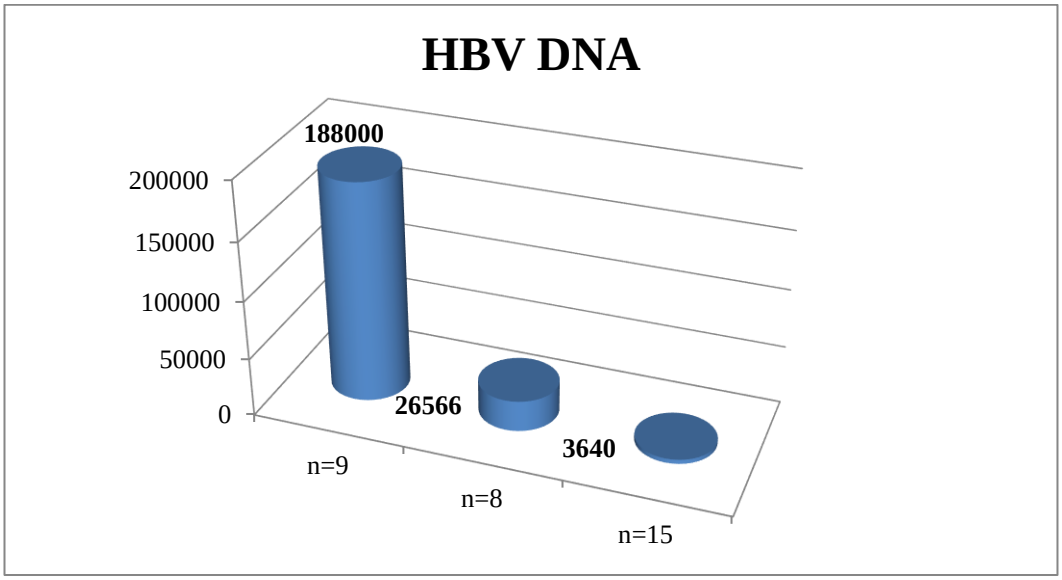

Fig. 1. HBV DNA level in liver biopsy specimens in patients with HDV infection in the absence of it in blood plasma (n = 32).

Despite the induction of endogenous IFN β and λ HDV in the hepatocyte by the virus (1,6), suppression of HBV DNA replication does not occur in our studies, which indicates the presence of a sufficient amount of HBV DNA in hepatocytes.

The absence of HBV DNA in blood plasma is explained by the fact that both HDV and HBV genomes continue to replicate in the infected nuclei of hepatocytes, along with this, the synthesis of HBsAg in minichromosomes (ccc DNA) continues. The HBV and HDV genomes require HBsAg to be released from the hepatocyte. Replication of HDV RNA is faster than replication of HBV DNA, since the hepatitis B virus genome is a double-stranded circular DNA of about 3200 nucleotides in length (2), and the size of the HDV genome is only 1672-1697 nucleotides (5), which indicates the possibility of faster replication of HDV than HBV. Thus, the HDV genome consumes more HBsAg and faster than the HBV genome. Due to the lack of HBsAg, the HBV genome remains in the cell, since HBV DNA must be wrapped in its "surface" antigen (HBsAg) to leave the hepatocyte. Thus, HBV DNA accumulates in the hepatocyte, without penetrating into the sinusoids and into the blood. This mechanism can explain the absence of HBV DNA in blood plasma in patients with active Delta infection.

To assess the effectiveness of AN therapy, we studied the viral load in HBV DNA in liver biopsy specimens of patients with CVHB and D with negative PCR for HBV DNA in blood plasma.

It was found that in 18 patients taking tenofovir disoproxil fumarate 300 mg / day, the average level was 10895 copies / ml. and ranged between 10^3 and 10^4 degrees. In 6 patients taking antiviral therapy, HBV DNA was 10^4 degrees and the mean HBV DNA level in liver biopsy was 25083 copies / ml. In 12 patients receiving antiviral therapy, HBV DNA in liver biopsy was 10^3 degrees and the average level was 3801 copies / ml. In patients who did not take tenofovir disoproxil fumarate, the amount of HBV DNA in the liver biopsy ranged between 10^4 and 10^5 degrees, and the average HBV DNA was 126501 copies / ml. (Fig. 2.).

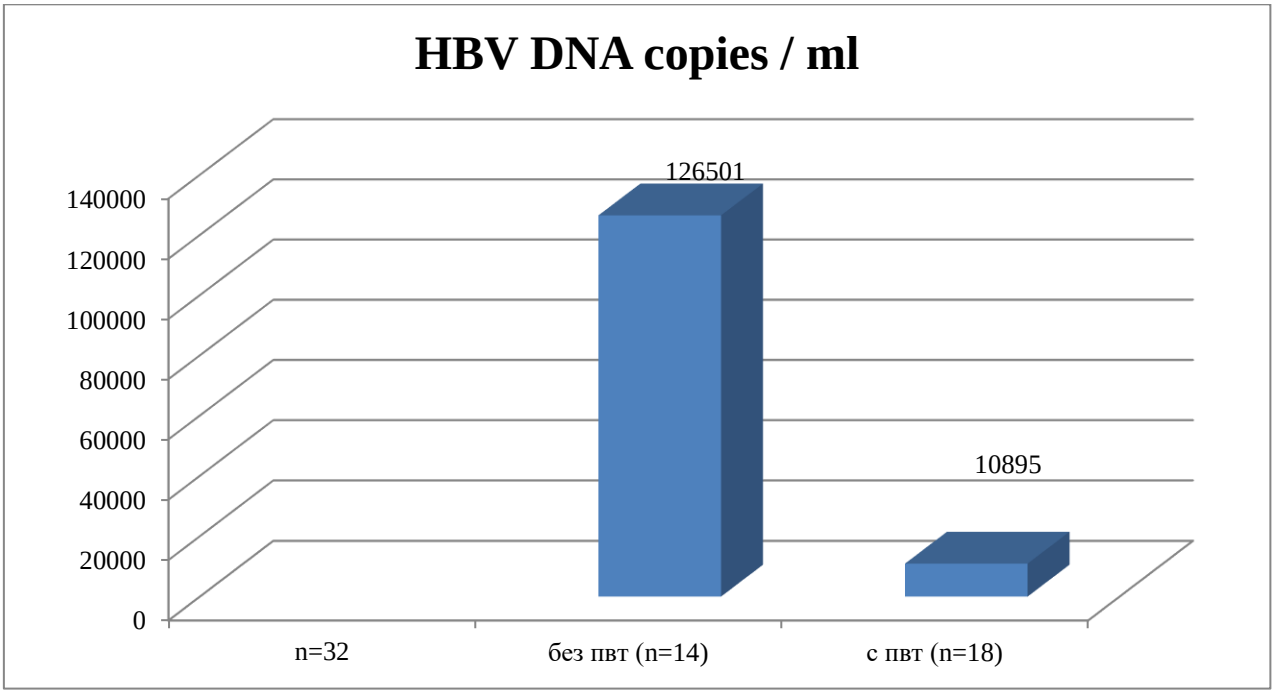

Fig. 2. HBV DNA level in liver biopsy specimens in patients with HDV infection, depending on the use of AN (n = 32)

From the above, it follows that patients with HBV and HDV coinfection are justified in the appointment of antiviral drugs (AN) to suppress HBV DNA replication..

CONCLUSION

1. In patients with HBV and HDV coinfection, liver biopsies show a high content of HBV DNA. In HBV and HDV coinfection, the absence of HBV DNA in the blood is not evidence of the absence of HBV DNA replication in hepatocytes.
2. In patients taking antiviral therapy - tenofovir disoproxil fumarate 300 mg / day, the average level of HBV DNA was 10895 copies / ml, while in patients who did not take antiviral therapy, the average level of HBV DNA was 126501 copies / ml, which exceeded 11.6 times relative to those taking antiviral therapy.
3. Patients with co-infection with HBV and HDV in the presence of the amount of HBV DNA in the biopsy specimen, it will be reasonable to prescribe antiviral drugs (AN) to suppress HBV DNA replication.

SEMANTIC-PHONETIC FEATURES OF SOME PHRASEOLOGISMS IN THE KARAKALPAK LANGUAGE

Yusupova Biybisanem Turdybaevna*

*Associate Professor,
Karakalpak Language, Candidate of Philological Sciences,
NSPI named after Azhiniyaz, UZBEKISTAN

ABSTRACT

Phraseologisms in the Karakalpak language are the most unique and wonderful manifestations of his vocabulary, language art, language skills and eloquence, in common, art of speech. Phraseologisms can express all aspects of a person's life, artistically reflect his life, customs and traditions, views on the environment. Therefore, they live as an integral part of folk culture and spiritual life. Phraseologisms are characterized by phonetic harmony, structure, meanings, stylistic differences and a number of other differences. The article deals with the issues of artistic formation of repetition of identical or similar sounds in the beginning of the word in the components of some phraseology in the Karakalpak language and their relation to the meaning.

KEYWORDS:*Phraseologism, Sound (Phonetic) Repetition, Phraseological Meaning, Alliteration, Assonance.*

INTRODUCTION

The Karakalpak people have a unique ability to spell words, to change and use words by artisticizing, idioms, sharpening the meaning, to wrap the word with emotion where it is needed, to make a "good word - the food of the soul", to tell the word where necessary and to reach the listener to his place , all of them are wonderful and priceless manifestations of Karakalpak art of speech, among which the phraseologies created by the people is a unique, very impressive, uniquely artistic, very figurative example of this art. Phraseologisms are the pride, beauty and wealth of the national language. Phraseologisms, which is one of the most valuable and precious vocabularies for the Karakalpak nation, have its unique beauty and sharpness of meaning, richly varied, figurative meaning and figurative with phonetic decoration, as well as its historical feature related to the far past and complex quality and a wide variety of symbols. Phraseologisms, which are inextricably linked with the language, culture, literature, history, spiritual world, all aspects of life, are an indispensable tool for the speaker and listener, writer and reader, and a unique way of depicting and decorating ideas. There is a great opportunity to convey ideas clearly, concisely, sharply and effectively through phraseology. Masters of speech skillfully use such artistic opportunities, enrich the language of their works, and create an impression. For example: Zhas basima “Biy bolayin” degen zhok edim, gilen zhasi ulkenlerimizdin akmakligi, ***komeshine kul tarta bergenligi*** tilimdi qishita berdi, buginin korip,

ertenin kormegen adamnin qoriqpaq kerek, goshshim, sondaylarga soyley – soyley tilim shigip ketti (I didn't say "May I be Biy (Chief)" when I was young, the stupidity of our elders, their ***thinking only themselves*** made me tell, you should be afraid of someone who sees today and does not see tomorrow, my dear, I become rude after speaking at them much. (Sh.S.) Komesh found in the component structure of the phraseologism is an old word (archaic) from the modern point of view in the Karakalpak language, the meaning of which is given in the explanatory dictionary as follows:

“Komesh. noun. A small loaf of bread baked in a box. Har Kim oz komeshinin tez piskenin tawir korip, shoqti oz komeshine kop tartadi (Everyone likes that their bread bakes quickly and pulls fire to their bread). (A. Dabylov) 2. Own profit, own benefit. Oz komeshine kul tartiw means is to think of one's own profit, one's own benefit. " [4,15] By paying attention to the origin, emergence and development of phraseologies, most of them are initially free vocabularies, in which the signs, things or actions specified in those vocabularies are performed, and over time, they have changed into a figurative, portable phraseologism. In fact, it can be seen that the desired action, performed for a specific purpose, has moved to another variable meaning and has made a phraseological meaning. Therefore, the construction of vowel combinations in such phraseologies, in some cases, the same or similar sounds, is closely related to their meanings. Here the main necessary thing, tool for komesh and it’s cooking – kul is similar with the phonetic aspects of the word, which also includes the influential, figurative, variable aspects of the formation of phraseologism. Thus, all of this forms a coherent phraseologism. Such phraseological units in the Karakalpak language differ with their specific artistry, role and function.

“Phraseologisms are a product of folk education. Therefore, they reflect a clear place, the economic system, history, culture, way of life, customs of the people, worldviews of linguists, and so on. The emergence and formation of phraseologies is associated with certain historical processes, social center, political and spiritual views. Therefore, the study of phraseologies from a historical point of view gives good results. ”[5,231] Also, the study of other characteristic features of phraseology allows to reveal their specific nature in a single, unified form.

The sound artistry and sound harmony in such stable units are found in phraseologisms which diverse by semantics. For example: Birak, hesh kanday ***basi bayli*** zhuwmakka kele almay-ak koydik. (But we could not come to any ***total*** conclusion). (O.Kh.)

Taban tirep oz dalasina,	**struggled** on his field,
Massagetler – shol barisi,	Massagets are a desert leopard
Ulli darya zhagasinda	On the banks of the great River
Turdi soytip kasarisip.	Stayed being stubborn. (I.Yu.)

“In most cases, it is possible to enter another word or words between the components of a phrase. In this case, the syntactic form of the phrase expands. However, in this way, its semantic integrity and the weight in which it acquires the status of a phrase are preserved”. [11, 19]. In this case, the speaker or the writer aims to distinguish something, and emphasize it. For example: Hatteki, “gawashalardin soliwina tiyim saliw sonin gana **kolinan keledi**” dep te oyladi (he even thought that "this is the only he is **able** to stop the extinction of gourds)" (O.Kh). Agronomlardin, ilimpazlarin **kolinan** bu isti duzetiw **kelermeken**? (Will agronomists and scientists **be able** to correct this work?)(O.Kh). And the following phraseology, which came with this **kol** component, has a different meaning: - Ilazh zhok. Ne desen de **kolin kelip tur**, - dep moyinladi Hakimbay (There is no cure. Whatever you say, you **win**, - admitted Hakimbay) (J.H). This phraseology means "koli kelip tur – luck, success" [7,113]. There are other phraseologisms that combine this word kol with other parts of body in sound combination. For example: Zhahangirdin egini

pispey, **kuri kol** pisi kurip kaliwga karaganin kaladagi zher bolimindegiler de, “Soyuz kosshinin” adamlari da biletugin edi (Both the people in the land department of the city and the people of the "Union Army" knew that Jahangir would be upset with **empty hand**, not growing his crops) (O.Kh). Olay bolsa, minekey, **tort koz tuwelmiz**, kapir ham kudaydan bezgen Zhahangirdin gellesin kim aladi? – dedi azgantaydan son bir shokip, eki karagan karakshi hakkedey tum-tusina zhalt-zhalt karap. (So, now, we are **together**, who will take the head of Zhahangir, infidel and atheist? - he said after a while, glancing like a pirate magpie that once bite, looked twice)(O.Kh). Kempir **tobeden tuskendey** birden bina bolgan bul hadiysege gubir-gubir tonkildandi (The old woman **suddenly froze** at this event and said to herself loudly). (O.Kh.) Erten azannan baslap Zhahangirdi atyzda korinler. Sondai isleimen, eger tanlaylarynyz takyldamasa, magan kelinler ... (See Jahangir at the field from the morning tomorrow. I’ll do , if you aren’t surprised, come to me…) (O.Kh.) Gey birewler patefonnan kozin almay, **awzin aship kaldi** (Some people **amazed** not taking their eyes off the gramophone. (O.Kh.) Here effectively conveys the meanings: kuri kol means empty hand, tort koz tuwelmiz - "everybody is here, everybody participate", [2,145] tobeden tuskendey - suddenly, tanlaylariniz takildamasa - not to be surprised, awzin aship kaldi – to be amazed.

In the components of some phraseologisms in the Karakalpak language, the artistic formation of repetitive identical or similar sounds at the beginning of a word is recognized as one of their differences. This requires not only the simple set of sounds, but also the combination of semantic and vowel combinations, thereby preserving the integrity of the phraseological meaning. Phraseologisms of this nature are distinguished by their semantic and phonetic art. For example: Bunin astarinda bir gap boliwi kerek, koyip tura ber, **Aytannin tarpiwina tussen** ele sen-am kizik bolasan!(There must be something behind this, just put it down, if you **fall under Aitan’s pressure**, you will be funny too!) (M.N.) In this case, the phraseology tarpiwina tusiw - means to fall into the hands of a person, to fall under pressure, to be biased, to relate, to submit to him in some way. And the phraseology takimina tusiw - means to belong to one person, to submit to his domination, to have his will, power, freedom in his hands, to be in his hands, for example, to be in his hands out of helplessness and to be in his marriage: Men bolsam, naylazhliktan Kalimbet baydin takimina tustim. (I’m, out of desperation, in Kalimbet bay’s hand). (O.Kh.)

There are several other (non-euphonic) phraseologies associated with this word takim. For example: Bul zhuwaday solgir, zhalgizimdi **takimina basip**, kokpar oynagani azday, ozin kok ala koyday etip sabagan, kaynaga! (The scoundrel **crushed my only son**, he not only played kokpar, but also beat him like a blue white sheep, brother-in-law!). (J.S.) Endi on zhildan keyin ozindi **takimina baspaydi** dep oylaysan ba? (Do you think that in ten years you will not **be suffered**?)(J.S.). Koli kizilga tiygen zhengen agana **takim burawdi salmas** pa eken? (Wouldn't your sister-in-law who had a daughter-in-law **excruciate** your brother?) (K.S.). – Balam! – dedi Allamurat suwpi, Eshbayzhannin **takimi bos kaldi**. (- My child! - said Allamurat Suupy, Eshbayzhan has no close friend). (J.S.)

In connection with the word takym, I. Kenesbayev explains the meanings of the following phraseologies in the Kazakh language: “takimga aldi – to be confused; takimga basti - 1. rode (the horse - B.Yu.); 2. turned; takym zhazdi - means to walk; takim kakkizbadi - it is said that the horse is fast and does not hit the whip; takim saldi - rode a horse; takimi tolari zhok -There is no one who is grateful and satisfied; takimi zharimagan - old. in the sense that the wife is unstable; takimi [atka …] zharimadi - there was no riding vehicle; takimi keppes uri – enterprising thief; takimina at tiydi – to have a horse under him; takimi tartti - a word that symbolizes a folk ritual (meaning "to have a horse", "Someone meets a woman"); takimi tolmadi - disregard . [3,488-489] In the examples, takimina basip - crushing, tormenting, subjugating, takimina baspaydi dep oylaysanba - not to humiliate, not to torment, not to take revenge, takim burawdi saliw – torment, excruciate, investigate, takimi bos kaldi - in accordance with the context, not to have a

secretive, sympathetic friend, a close person; and means that to have no one, that he could compete, that he was equal to himself. In such phraseologies, the national spirit is clearly felt.

J.B. Satkenova, N.K. Bisegalieva: “Every writer uses linguistic descriptive tools to convey the image of the hero and his true nature. However, the writer analyzes and selects them according to his stylistic and linguistic tastes. In particular, the role of phraseology in the use of the writer, in the image of the hero of the author's use is special. Artistic devices allow to accurately conveying the character's behavior, psychological state, and emotions". [9,215]. Narbay **salisi suwga ketken kisidey sam-saz bolip, kabaginin astinan karap** tur eken (Narbai looked under his eyebrows **as if he was thinking deeply**). (O.Kh) Jahangir ozinin katalligin da, ogiri ojetligin de, geyde adamlarga **katti kayirim soz** aytatuginin da, soytip, kopshilikti irenzhitip zhurgenin de sezbedi. Ati salgan zherden zhorgalap, hesh kim betine zhel bolip tiymegen son, ol ozinin **katti ketkenin** kaydan bilsin? (Jahangir did not feel his cruelty, his stubbornness, **his harsh words** to some people, and his disgust with the masses. How could he know that he **had gone so far** as nobody touched or spoke him at face?) (O.Kh.)

The people have formed many idioms based on their life experiences. Phraseologisms serve as an important tool in the implementation of his ideas, reflecting the views of the people on life, person, the environment. Among them, the phrases of euphonic nature, which have sound repetitions in their components, are known for their special artistry and expressiveness. For example: Qalay degen menen ol **ko’pti ko’rgen**, ko’p biletug’in haqiyqat diyqan adam. (He is a truthful farmer who has **seen a lot** and knows a lot). (O.Kh.) Bilsem ozinnen **bir ko’ylek burin tozdirg’andi** ko’rsen, onin menen so’ylesip ken’es soraw, hal-jayin biliwge qiziqsiniwin kishi peyilligi g’oy” dep oyladi ol jo’ninde. (I know that if you see **older than you**, it is humane to talk to him and ask for advice, to be interested in the situation”, he thought about it). (O.Kh.) Jahangir o’mirinin ko’binshe **aytqani aytqan, degeni degen bolip**, o’jet ha’m g’iris o’sti. Asirese, uyinin’ ishinde hesh bir bende onin’ aytqanin tin’lamay, hesh adam **so’zin sindirg’an emes**. (Zhahangir's life was mostly as he **had everything he wanted** and grew stubborn and rude. In particular, no one in the house listened to him and **did not refuse his word**). (O.Kh.) Hayalinin’ **otirg’an jeri oziniki bolip**, boyin qiya tasladi da, darhal uyqig’a ketti (As his wife's **too tired**, she fell down and immediately fell asleep). (O. Kh) Birewler “Bul tuqim shigitten kelgen ba’le” dese, ekinshi adam “Joq, olay emes, ba’le jerdin’ o’zinen” dep, har qiyli pikirlerdin’ basin shatpaqlap, **siniqqa siltaw** izledi. (Some said “this trouble is from the crop seeds”, another man said “No, not like this, trouble from the earth itself”, thought all the opinions, and **looked for the reason**). (O.Kh.) In this case, the **ko’pti ko’rgen** (see a lot) alliterative phraseology is used as a synonym for a **ko’p biletug’in** (know a lot), but in addition to this meaning, the meaning of an older, more experienced is meant by the phraseologism **o’zin’nen bir ko’ylek burin tozdirg’an**. And the unit of **aytqani aytqan, degeni degen boliw** is an equal two-component phraseologism – has an alliteration-assonant feature, **so’zin sindirg’an emes** - it means that the word has not been refused, it has been fulfilled. The meaning of extreme fatigue is expressed through phraseologism **otirg’an jeri o’ziniki bolip**, which is told to a person (mostly women) who is not active, not quick, and moves slowly and heavily. Siniqqa siltaw izlew - is phraseologism in the sense of restraint, finding a reason, searching for a reason, all of them are impressive not only by the semantic, but also by the phonetic artistry.

"Euphony is created by the repetition of same sounds or groups of sounds." [10,23] Euphony in phraseologies increases their effectiveness and imagery. For example:Taqir jerden shan’

shig'arip, jesir dawi barma, urisqan barma, talasqan barma, solardi dawg'a aylandirip, birnen'e shig'arip juriw kerek, bolmasa **qazan qaynamaydi**. (Makes trouble from nothing, if there's a widow, blusterer, arguing man, turned all of them into quarrels and it's necessary to make something, otherwise **there's nothing to eat**). (K.A.) Ol jayga siymay ketti. **To'rt diywal to'rt ta'repinen qisip baratir**. (He could not fit in the room. He **is getting bored**). (K.S.) Xaliq **qulaq qoyip** tin'lay beredi. (The people will listen **attentively**). (K.S.) Biyil enesi qaytis bolgali Biybirawshan atasinin' awizina qarawdi urdiske aynaldirgan edi. **Aytqanin xat penen qalemdey** koredi. (This year, after the death of his mother-in-law, Biybiravshan made it a habit to listen to his father-in-law's mouth. She considers everything **what he says as a rule**). (K.S.) **Orninan o'rre turdi** da, sirtqa zip berdi. (He **got up** and ran out). (K.S.) **Jo'ndi-josaqti bilmey**, halalani sala beredi (He does **not know the situation** and continues to make a noise). (K.A.)

Some proverbs in the Karakalpak language are used in a phraseological sense, as well as phraseological expressions of gratitude and cursing, built on the harmony of some phonetic harmony, are characterized by their sharpness and special impact. For example: En' bolmasa **quwis uyden quri shiqpay**, nan awiz tiysin, bala paqir. (At least he should have a little bread without leaving the house with empty hand, poor child). (O.Kh.) – Qoy, kempir, sen olay deme. Ko'zimnin' tirisinde ma'n'gi birge bolasan', bilsem. Sol ushin "erli-zayipli, **qosag'in meneb qosa ag'ar**" deydi. (No, my old lady, don't say that. I wish we were together forever when I'm alive. That is why it is said that "a couple should be old equally, live together until both of them die). (OKh.) **Topirag'I torqa bolg'ir** paqir murap edi g'oy. (he was worker, may his place be in heaven). (K.S.) **Jatqan jerlerin' jariq, topiraqlardin' torqa bolg'ir** ag'alarim-ay! (**may your places be in heaven**, my brothers!). (K.S.)

"The phraseologisms which is different with its imagery is a distinctive manifestation of the language of each nation. The very widespread use of the phraseologisms in the literary work reflects the national identity". [8,40] Such phraseologies are also part of the national language of the Karakalpak people. They are impressive and artistic, both in meaning and sound. For example: Burin bolg'anda g'oy **bastiriliwli qazan bastiriliwli qala** berer edi (In the past, **a closed pot would remain closed (all secrets would be saved**)). (K.S.) Hayali da ser salip edi, **juregi suw ete** qaldi. (When the wife also glanced, his **heart was cold (afraid)**). (K.S.) Jan'g'izinin qanli maydang'a atlanar aldi alti qanatli uyge bir o'zi siymay poshalap, **ingendey qayisip, botaday bozlap otirg'an** Nazli kempir juregindegi da'rtine usinnan basqa shipa taba almadi ma, kim bilsin, qiza kele aytinip jiladi. (Before going to the bloody battle of Zhangyzy, **poor crying** Nazli old woman, who was alone in a six-roomed house, could not find a cure for her heartache, who knows, she cried). (KS) Sonnan son' "**o'lim-o'lim bir o'lim**" dep aqsaqal bolistin' qorlig'ina ko'nbey qarsi boldiq (Then we protested against the humiliation of the aksakal, saying "**death is death**"). (K.A.)

In the Karakalpak language there are such phrases as **tuyeden postin taslag'anday, at-tonin al qashadi, tonin teris kiyiw** and others in connection with the words of the ton, skin of the animal. They are used by masters of speech in the literary works with some changes for the stylistic purposes. For example: Geyde **at-tonin teris awdarip kiygen** ba'le meterge uqsap ketedi. (Sometimes he looks illness which is **angry**). (K.S)

The skill of the people in life is clearly reflected in the phraseologies created similar to the convenience or inconvenience of using something, or in comparison with it. For example: Qap, **quyisqang'a qistirilg'an tezektey bolip**, bul da qalmadi aw, bir jag'imizdan. (A bag is **like stuck to the bent**, and it's not also left, on the one hand. (K.A.) In various literatures, the word "bent" is interpreted in connection with the horse's bridle: "the bent means it's hanged loosely to the horse's tail in order not to move the saddle forward [12,293]. "Quyisqan - it's hanged loosely to the horse's tail in order not to move the saddle forward. It is used in some dialects of the Kyrgyz language in the form of "quyushqan "[1,114]. "Also, in order to tie the saddle, the naked body of the horse is covered with sweat, on the sweat the pillow will be put, in order not to hurt the horse's skin the girth will be tied, and the bottoms are tied, and at the end it's tied with bent [6,27]. As it is known, this phraseology, which appeared in a variable sense due to the fact that the dung is stuck to the bent, cause inconvenience, lack of opportunities to do something, something is attached, something is added, carrying something that is not needed, not to let to do something, in the sense of obstruction.

Thus, phraseology is an artistic example of the vernacular and differs as a means of expressive and effective communication. They are especially impressive and figurative, as well as also become artistic with the repetition of similar or identical sounds. The study of phraseologisms based on such phonetic artistry in the Karakalpak language, and their evaluation from a phonostylistic point of view revealed one of their individual features.

A GLANCE AT THE SECURITY RISKS ASSOCIATED WITH CLOUD COMPUTING

Dr. Kashif Qureshi*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: kqureshi.cse@sanskriti.edu.in

ABSTRACT

Cloud computing has gotten a lot of attention in the new age of IT technologies because of the growing need for services or utility computing all over the internet. The security risk posed by resource sharing in cloud computing has emerged as one of the most difficult issues to address when offering powerful processing and storage as on-demand services. Governments and businesses all over the world are encouraged to develop or move to the cloud because of the cheap cost associated with the increased efficiency and performance enabled by cloud computing. However, there are still a number of technological problems related to cloud computing's features and the supply of high-quality service, causing a delay in cloud adoption. The security dangers and difficulties of cloud computing are highlighted in this review paper, as well as the security requirements for cloud computing. The main goal of this study is to categorize the security risks and difficulties associated with various types of cloud computing (SaaS, PaaS and IaaS).

KEYWORDS: *Cloud Computing, Cloud Security, Infrastructure As A Service (Iaas), Platform As A Service (Paas), Software As A Service (Saas).*

33. INTRODUCTION

Cloud computing has exploded in popularity, with Microsoft, Google, and a slew of other companies migrating to the cloud in recent years. Cloud computing is the separation of software from the operating system and hardware, and it is not the same as virtual computing. Because the program is no longer reliant on the hardware or operating system, it will automatically move to alternative resources if they fail. The word "cloud" refers to a distant datacenter, according to a researcher[1]. It also has two interpretations. The first is the use of a Web browser to access information and data resources on the Internet. The second option is to pay for computer resources depending on their use. The National Institute of Standards and Technology (NIST) defines cloud computing as a model for providing universal, suitable, on-demand network access to a pool of configurable computing resources (e.g., servers, networks, applications, storage, and services) that can be quickly released and provisioned with minimal management effort or service provider interaction[2], [3]. Furthermore, Gartner describes cloud computing as a kind of

massively scalable computing style that allows competent and deliverable IT as services to external consumers through internet technologies. Another researcher defines cloud computing as the infrastructure paradigm change that allows SaaS to rise to prominence. It's a collection of web-based services targeted at allowing consumers to get a wide variety of functional capabilities on a pay-as-you-go basis, which traditionally required significant hardware/software expenditures and professional expertise to achieve. Furthermore, one author defines cloud computing as a storage system that allows users to access files from anywhere on the internet using any technology by storing data on a cloud server rather than a conventional computer.

For hardware and server virtualization, cloud computing employs virtualization techniques as well as automated decision-making. Instead of executing one application on a server using conventional servers, cloud computing offers clients with a virtual infrastructure where they can simply store and execute software while sharing server resources for many applications utilizing virtualization methods. Using a hypervisor to perform virtualization, it is feasible to run many programs on a single server. Cloud services include Outlook, Facebook, Gmail, Google Docs, and YouTube[4]. Cloud computing is a term that refers to services that are provided via the internet.

Measured service, wide network access on-demand self-service, fast flexibility, and resource pooling are the five fundamental features of cloud computing. It is intended to improve the efficiency and performance of computer systems while reducing costs. According to a study, 91 percent of organizations and businesses in Europe and the United States choose to move to the cloud because of the cost savings enabled by cloud computing.

34. DISCUSSION

34.1. Cloud Main Forms:

Based on the kinds of services they may offer to clients, cloud computing systems can be divided into three groups. Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS) are the three types of services (IaaS)[5]. The following are descriptions of the three kinds of services.

34.1.1. Software as a Service (SaaS):

It is a kind of cloud computing that offers end users services such as applications, computational processes, and storage, all of which may be accessed remotely[6]. Fixed subscription and usage-based price plan models are two examples of cost plan models for such a service. The program may be operated via a network, with a thin client serving as the user interface. Table 1 lists some examples of SaaS providers.

TABLE 1: ILLUSTRATES THE LIST OF SOFTWARE AS A SERVICE (SAAS) PROVIDERS ALONG WITH THE SERVICES OFFERED BY THEM[7].

Name	Service provided
Drobox and SkyDrive from Microsoft	Files and folders storage service
Salesforce	Online CRM (Customer Relationship Management)
Live Mesh from Microsoft	Files and folders to be shared and synchronized across multiple devices.
Outlook from Microsoft	Email and documents processing service
Open ID and OAuth	Identity service
Amazon Simple Queue Service	Integration service
Google Maps, Bing maps and Yahoo! Maps	Mapping service
Google Checkout, Amazon Flexible Payments Service, PayPal	Payments service
Google Search, Yahoo! BOSS, Alexa	Search service

34.1.2. Platform as a Service (PaaS):

It's a kind of cloud computing service that gives developers a highly integrated environment in which to create, test, and deploy practice applications[8]. However, there are certain constraints that developers must consider when deploying software in this kind of service and trading software scalability for software scalability. PaaS providers are included in Table 2 as examples.

TABLE 2: ILLUSTRATES THE LIST OF PLATFORM AS A SERVICE (PAAS) PROVIDERS ALONG WITH THE SERVICES OFFERED BY THEM[8].

Name	Service provided
Google's App Engine	Build Web applications and its Web application frameworks
Godaddy	Build Web applications and hosting
Heroku	Ruby on Rails for building Web applications
Mosso	Web hosting
Microsoft Azure	Proprietary
Force.com	Proprietary

34.1.3. Infrastructure as a service (IaaS):

It's a kind of cloud computing that focuses on providing IT for system administrators by supplying hardware, software, and equipment to provide software application environments with a resource usage-based pricing model[9]. IaaS may automatically scale up or down in response to an application's resource requirements. With a fixed utility price model, IaaS computing processes and storage infrastructures are accessible to the public.

34.1.4. Anything(X) as a service (XaaS):

It is a subset of cloud computing that was originally defined in 2008. It all comes down to sharing the hardware's capabilities with the software[10]. Network as a Service (NaaS), Database as a Service (DBaaS), Monitoring as a Service (MaaS), Desktop as a Service (DaaS), and

Content distribution as a Service are just a few examples of what will be feasible and achievable via virtualization.

34.1.5. Component as a service (CaaS):

It has to do with services that offer an API for web services so that they may be used as a component. CaaS, for example, may be offered as end-to-end business services through their API's SaaS services.

34.2. Types of Cloud:

The customer may select from a variety of cloud computing architectures, based on the hardware and software required as well as the pricing. In general, cloud architecture is as follows.

34.2.1. Public Cloud:

This kind of cloud computing architecture is designed for clients as a consumption plan payment model with a pay-as-you-go payment mechanism. Google App Engine, Microsoft Azure, and Amazon Web Services are examples of this kind.

34.2.2. Private Cloud:

This cloud computing architecture is designed for essential infrastructure as well as private businesses and organizations. This kind of cloud computing environment is not open to the general public. Commercial clouds include data centers for private businesses and government data centers.

34.2.3. Community Cloud:

It's a robust infrastructure that allows a third party to offer applications and platforms on which new services may be built, and it includes a variety of parties.

34.2.4. Hybrid Cloud:

The public and private clouds are combined in this kind of cloud computing architecture. The National Institute of Standards and Technologies (NIST) defines it as a hybrid cloud that combines public and private clouds and connects them using standardized or proprietary technology to allow data and application mobility.

Cloud computing, also known as utility computing, has exploded in popularity thanks to a slew of new service providers. These service providers provide on-demand cloud computing services, such as virtual servers and storage, allowing many consumers and businesses to migrate to the cloud and benefit from elastic and adaptable services.

The development of the wide global web, on the other hand, has aided the rapid increase of on-demand applications in recent years. The likelihood of cyberattacks has been steadily rising. As a result, security concerns about the risk factors for today's cloud computing architecture must be considered. As a result, the goal of this research is to bring attention to the present cloud computing architectural risk factors and associated problems, which are listed below.

34.3. Attacks And Threats In The Cloud Security:

The following are examples of cloud security assaults and threats:

34.3.1. Abuse And Nefarious Use Of Cloud Computing:

Assailants may utilize cloud computing capacity for cloud infrastructure to attack targets with spam and malware, such as botnets. It is the biggest security threat in cloud computing, according to the CSA.

34.3.2. Account And Service Hijacking:

It's one of the most dangerous security risks. It occurs when attackers plan to hack a web service on a website housed on a cloud server or service provider's infrastructure, then install their software that controls in the cloud provider's architecture.

34.3.3. Backdoor Channel Attacks:

This kind of attack occurs in IaaS when it provides a high degree of penetration to an effective user on the VM or Hypervisor level. This may have an impact on service availability and data security.

34.3.4. Cross Site Scripting Attacks:

It's also known as XSS. It's one of the most powerful security flaws discovered via online apps. The Java script language is one of the most often utilized scripting languages in such attacks.

34.3.5. Denial Of Service Attacks:

The service will not be accessible when the users plan to request it from the server in this kind of assault. They'll receive the 404 error, which means the service isn't available.

34.3.6. Cloud Malware Injection Attack:

This is one of the most dangerous cloud computing security threats, with the goal of injecting malware, macules applications, or virtual machines into the cloud architecture.

34.3.7. Insecure Application Programming Interface:

When service providers offer services to consumers through APIs, the APIs are encrypted with secure authentication, and secure access control and activity monitoring methods are included.

34.3.8. Metadata Spoofing Attack:

The web services providers provide the service metadata document to the client system, which contains all of the information about the service invocation, including security requirements, message format, and network location. The attacker's goal in this instance is to reengineer the web service metadata descriptions by requesting that the network references and endpoints to the security policies be changed.

34.3.9. Man In The Middle Attacks:

The hacker establishes an independent link between the client and the service provider in order to monitor the data and information for the service without the customer's awareness.

34.3.10. Malicious Insiders:

This kind of security danger occurs when there is a lack of security concern for how workers may use the service provider's virtual cloud assets. Because of the employee's privilege in not implementing in the cloud system and updating the responsibilities when their behavior or work changes, this danger may be more complicated.

34.3.11. Shared technology’s vulnerabilities:

This problem arose from cloud computing, which makes use of internet infrastructure that is shared across cloud clients. As a result, all of the existing issues with internet infrastructures will be transferred to the cloud. Traditional components, on the other hand, have not been designed to share resources in cloud computing systems.

34.3.12. Phishing Attack:

It's about invading the privacy of users and exposing their data and information by enabling them to visit a phony web link placed on their computers: malicious malware exposes that data.

34.3.13. SQL Injection Attacks:

This kind of problem occurs when hackers attempt to attack a website's database by injecting code into SQL statements through website query techniques, which may disable a website's security.

34.3.14. Sniffer attacks:

The attacker aims to read the content of the network packet in this kind of attack, even if no encryption techniques were used during the data transmission. Sniffer may be a program, a gadget, or a script.

34.3.15. Security concern with the virtual machine Manager:

The kind of security issue is that service providers must be very cautious about the services offered by VM technology to consumers since this technology has certain security flaws in some instances.

34.3.16. Zombie attack (DoS/DDoS):

It occurs when hosts are flooded indirectly or directly at the Hypervisor, Network, or VM level. It has the potential to disrupt service availability and establish a user account for unauthorized service use.

34.3.17. Unknown risk profile:

This kind of security danger arises as a consequence of focusing on the capabilities and features obtained from using cloud services without taking into account the security technologies and products that will be created. The issue is that third-party data may be accessed by features, and that this data may be released for any reason.

34.4. Cloud Computing Challenges:

34.4.1. Accounting:

In order to maintain network management, it is one of the important elements that must be evaluated while implementing services in cloud computing systems.

34.4.2. Access controls:

It is a problem for all service providers since it may lead to a security breach by exposing customer data and allowing hackers access to the organization's infrastructure.

34.4.3. Compliance:

Cloud computing has a flaw when it comes to enabling compliance management techniques. This may result in severe data security and privacy concerns.

34.4.4. Extensibility and Shared Responsibilities:

The security issue in cloud computing must be addressed by both service providers and consumers. Until recently, there has been no clear picture of how security obligations in cloud computing would be met.

34.4.5. Cross-Organizational Security Management:

The achievement and maintenance of security standards and compliance with SLAs is a major issue in cloud computing. To guarantee that an acceptable security need in cloud computing is met, it is necessary to establish a corporation among companies.

34.4.6. Private Cloud:

Because the phrase "private cloud" means "on-premises," it's safe to assume that the working environment will be similar to conventional computing. Computing resources may be virtually extended or de-extended based on the requirements of the user by using virtualization technologies. The whole organization's departments will have access to common resources as a result of this. However, this has not yet been completely applied across a broad spectrum of businesses. In other words, it is a step in the right direction for public cloud services to take.

34.4.7. Identity management (IdM):

It is an important element of cloud computing security that aims to conduct verification and validation across diverse cloud services. However, there are still some problems with compatibility among the most recent security solutions.

34.4.8. Heterogeneity:

When many service providers offer a large number of services utilizing diverse technologies, a heterogeneous problem arises. Heterogeneity may occur as a consequence of variations in software and hardware.

34.4.9. Integration:

Customers and organizations who need to use numerous service providers for a variety of reasons must deploy and integrate software and data across different clouds. Hybrid clouds may help address this problem in certain situations.

34.4.10. Bandwidth requirements:

Organizations must analyze the communication bandwidth needs and appraise the services in terms of significant amounts of data transfer before adopting a cloud service.

34.4.11. Performance:

Although cloud computing reduces costs, performance problems such as connection time between users and cloud services have become a problem as the number of users grows, so does the quantity of information and data that must be transmitted to them. This puts a lot of strain on the hardware and software. Another reason is that the user and service providers are separated by a significant distance. Customers may also scale up their cloud infrastructure beyond their initial expectations, posing a significant issue for service providers.

34.4.12. Monitoring:

When cloud computing is built on service monitoring, there will be a huge need for monitoring to be used across all cloud services and activities, whether in public or private infrastructure.

34.4.13. Service Level Agreement:

It's an essential part of a cloud service customer's and cloud service provider's contractual relationship. Because of the worldwide nature of the cloud, SLAs often cover several countries, each with its own set of regulatory obligations, particularly when it comes to the security of personal data stored in the cloud.

34.4.14. Risk analysis and management:

It is a critical component of cloud security. It's all about reducing cloud computing's noisy capacity by screening and detecting any risks before delivering the service to consumers.

34.4.15. Virtualization:

It is a method of delivering cloud services to consumers, particularly when using IaaS services, although it still has security concerns.

34.4.16. Security in the web browser:

In terms of complicated and sophisticated banking and crucial settings for a shared solution, such as cloud solutions, the security standards in the web browser are insufficient to meet the user's demands.

34.4.17. Policies:

A well-written policy for the security processes and standards that will be applied in cloud computing systems is required.

35. CONCLUSION

Cloud computing has recently sparked a lot of attention in the business and academia, since it reflects the backbone of future contemporary civilizations. Cloud computing improves economic efficiency while lowering expenses. Governments, organizations, and businesses are seeking for cloud computing's enabling characteristics. However, without appropriate answers for a significant number of security threats and privacy concerns, cloud computing adoption will remain a long way off in the coming years. The most recent dangers and difficulties of cloud computing have been highlighted in this study. Our future study will focus on developing a security model that takes into account the highlighted threats and difficulties.

ABSTRACT

Cloud computing has the ability to provide consumers with cost-effective and more flexible services on demand via the network. It expands the organization's capabilities without the need to hire new employees, invest in new infrastructure, or purchase new software. Because of the scalability of resources, cloud computing has expanded significantly in recent years, and it now seems to be a fast-growing sector of the IT business. By analyzing policy failure or malicious behavior, the dynamic and scalable nature of cloud computing presents security difficulties in their administration. The comprehensive design of cloud computing architecture is examined in this article, which includes deployment models, service models, cloud components, and cloud security. Furthermore, this research highlights the security issues in cloud computing during data transmission and proposes a feasible method to mitigate the possible risks. The aim of a Trusted Third Party (TTP) is to provide security features that are adequate in cloud computing. The Public Key Infrastructure (PKI) is a cryptography-based security solution that works with Single-Sign-On (SSO) and Lightweight Directory Access Protocol (LDAP) to guarantee the integrity, confidentiality, availability, and authenticity of communications and data.

KEYWORDS: *Cloud Computing, Cloud Security, Cryptography, Deployment Models, Service Models.*

36. INTRODUCTION

Cloud computing expands information technology capabilities by dynamically expanding capacity and adding features without the need to invest in big and costly equipment, software license, or new personnel training. Cloud computing offers a more flexible method to access storage and compute resources on demand, among other advantages[1]. Different business companies have increasingly realized in recent years that by utilizing cloud resources and gaining quick access, they can lower their initial business costs by paying only for the resources they use rather than having to invest in potentially large infrastructure (owning and maintaining). Rapid deployment, cost savings, and low investment are the primary motivators for many businesses to use cloud services. The National Institute of Standards and Technology (NIST) explains cloud computing as a paradigm for enabling easy, ubiquitous, and on-demand

network connectivity, with customizable computer resources that can be supplied and provisioned quickly with little administrative involvement[2].

The cloud is a collection of virtualized and linked computers that comprises of parallel and distributed systems that may dynamically present and supply computing resources depending on Service Level Agreements (SLAs) created by a settlement between consumers and service providers[3]. Infinite computing resources, cheap cost, security controls, hypervisor protection, fast elasticity, high scalability, and fault tolerant services with excellent performance are all benefits of cloud computing. Many businesses, such as Microsoft, Google, Amazon, IBM, and others, created cloud computing systems and improved their services to serve a huge number of consumers. Furthermore, there are major obstacles to adopting cloud computing, such as privacy concerns, compliance, and legal issues, since it is a relatively new computing paradigm with a considerable degree of uncertainty about the security at all levels, including host, network, data, and application. When databases and application software are moved from the cloud to big data centers, data and service management becomes a major issue. Many security issues may emerge when using cloud computing, including privacy and control, virtualization and accessibility flaws, credential and identity management, confidentiality, responder device authentication, and integrity. Because service providers guarantee a high degree of security, compliance, and regulatory compliance, the use of cloud computing and market maturity is constantly increasing. Cloud services will contribute to this expansion by providing greater flexibility and cost savings.

Cloud computing is enabled via virtualization technology, in which the host system runs a hypervisor program that creates one or more Virtual Machines (VMs) that accurately mimic real computers[4]. Any program, from the operating system to the end-user application, may be operated by these simulations. The number of physical devices in data centers is determined by the hardware level, which comprises hard drives, CPUs, and network devices. It is unaffected by the physical location that is in charge of processing and storing information as required. A mix of the virtualization layer, software layer, and management layer is used to manage the servers effectively[5]. The virtualization layer is used to offer the cloud components of fast elasticity, resource pooling, and location independence that are required. It is also a necessary component of cloud deployment. The management layer is in charge of implementing security policies and monitoring throughout the cloud.

This study breaks down cloud computing architecture into four categories: 1) cloud deployment methods, 2) cloud service model, 3) cloud fundamental features, and 4) cloud security. When data migrates to modernize cloud systems, advancements in business requirements, and the effect of services provided by various organizations to expand the market, different businesses' security issues with the rising significance of cloud resources are taken into consideration. Furthermore, this research focuses on identifying the security problems and challenges in cloud computing, taking into account threads, vulnerabilities, needs, and dangers, as well as discussing security solutions and recommendations for cloud computing. Also covered is the Trusted Third Party (TTP) in the cloud computing environment, which enables trust and cryptography to guarantee data integrity, authenticity, and secrecy while addressing particular security concerns. The proposed solution to the horizontal level services that are accessible for the relevant organizations to preserve confidence in order to implement the security mesh. Single-Sign-On (SSO) and Lightweight Directory Access Protocol (LDAP) are used in Public Key Infrastructure (PKI) to securely authenticate and identify the relevant entities.

The remainder of the paper is laid out as follows: Apart from presenting the analysis and debate based on the security problems found in the cloud computing environment, Section 2 highlights the comprehensive design of cloud computing architecture and discusses the security challenges of cloud computing. The research's findings and future work are presented in Section 3.

37. DISCUSSION

37.1. Cloud Computing Architecture:

NIST is in charge of ensuring security in the cloud computing environment as well as establishing standards and recommendations, which is an important contribution that helps people understand cloud services and computing technology better. The four deployment types of cloud computing architecture are public cloud, private cloud, community cloud, and hybrid cloud. The deployment models describe the many ways in which cloud services may be delivered via the computer infrastructure. Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS) are the three cloud service types or delivery methods accessible to customers. In a cloud environment, various degrees of security are needed for these service types. The cloud basic characteristic layer considers a broad variety of services that may be utilized over the internet. Services, resource allocation management, and security are all provided by the cloud service provider. The architecture describes the five main components, which are made up of cloud-based services. When transferring data or shared resources to the cloud using a client-server architecture, cloud security is a critical and difficult job. The architecture of cloud computing is shown in Fig. 1, and the following elements are discussed:

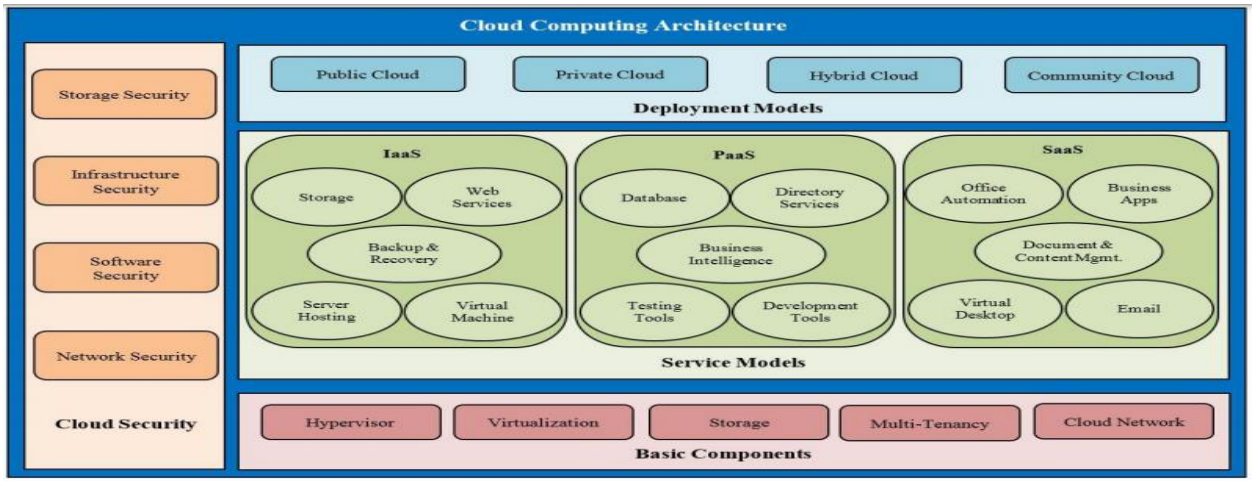

Fig. 1: Illustrates the Cloud Computing Architecture[6].

37.1.1. Cloud Deployment Models:

The cloud computing model describes the nature and purpose of the cloud and includes three deployment models that may be used to depict cloud service models. Fig. 2 depicts the deployment models, which are categorized as follows:

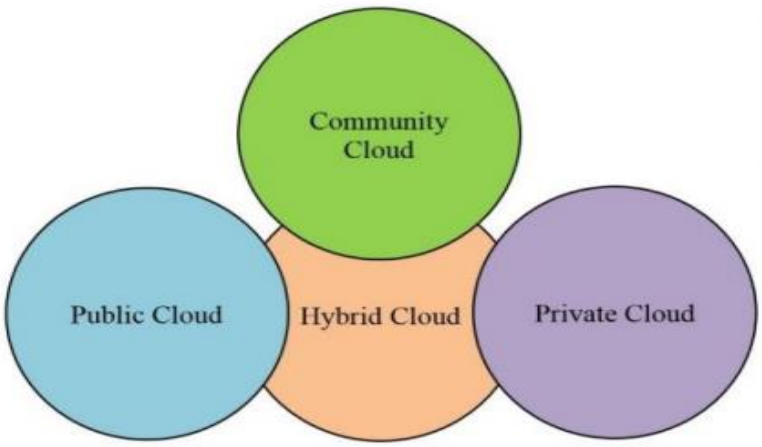

Fig. 2: Illustrates the different Cloud Deployment Models[7]

- **Public Cloud:**

A public cloud is a cloud that is hosted and controlled by a service provider, with a service level agreement between the customer and the resource provider. Cloud service providers include Microsoft, Google, Amazon, VMware, IBM, Sun, and Rackspace. The platform is built in the style of universal computing, and it can handle any kind of client demand. The materials are readily accessible and made available to the general audience. Multiple organizations are engaged in the operation of public clouds, and the resources are open to the public, making them challenging to defend against malicious assaults. Because it is outside the firewall, it raises certain issues about consumer privacy, data access, and security. It's less secure than the other deployment options, but it's ideal for small and medium businesses who don't need to set up servers or invest in money.

- **Private Cloud:**

A single company manages and maintains the cloud infrastructure, which serves numerous clients. If a company created their own private cloud and recently created their own servers with real hardware servers and a virtualization layer on top of them, resources would be accessible exclusively internally. So, instead of using Microsoft or Amazon servers, their program may be deployed to their own physical control server. They are going to build their own infrastructure. Because of its unique internal exposure, it can guarantee physical security and is more secure than the public cloud. The authorized stakeholder and organization get exclusive access to the private cloud. However, the cost is considerably greater since the server administrator, virtualization specialist, and network specialist all need skill and training. The cloud service provider's virtual application and scalable resources are pooled together and made accessible to clients to use and share. Because the infrastructure is managed and owned by the same company, it is simpler to handle the connection between the service provider and the client in the private cloud. It makes use of cloud management software's capabilities to guarantee a dependable delivery service and the integrity of external resources.

- **Hybrid Cloud:**

The term "hybrid cloud" refers to a cloud deployment model that combines two or more cloud deployment types, which may be public, private, or community clouds, while remaining distinct entities. The value of hybrid cloud is that it can provide more resources when a customer's demand is strong, and it can also be used to transfer certain computing tasks from private to public cloud. Because it provides more secure management of the apps and data, it is properly structured and allows various organizations to access data via the internet. It has advantages over other deployment options and may be hosted both inside and outside. Hybrid cloud is gaining traction and has established itself as a dominating paradigm. The primary reason is that it may benefit from the cost savings, scalability, and elasticity that public cloud can offer, as well as control flexibility when required.

- **Community Cloud:**

The term "community cloud" refers to an organization's cloud infrastructure being shared among customers with comparable interests or concerns, such as policy, security needs, purpose, and compliance considerations. We claim that the resources of the community cloud are operated, managed, shared, and handled by multiple organizations or a third party. Third-party IT services and solutions, such as those provided by Siemens, may be used to build up a media cloud for the media business. It is more uncommon and specialized. The community cloud infrastructure is shared and controlled by a variety of organizations, including research groups, businesses, and government agencies.

37.1.2. Cloud Service Models:

Cloud computing architecture consists of a collection of services that allow users to access customizable computing resources (applications, storage, servers, networks, and services) on demand, while also being dynamically scalable, virtualized, and multi-tenant[8]. It offers customers the flexibility they need to deal with quickly changing consumer needs while still providing a dependable solution. Many service providers (including Microsoft, Google, Amazon, Rackspace, and others) provide services for any of these models, including IaaS, PaaS, and SaaS. The categorization of cloud service models is critical for determining which service model meets and accomplishes each function. The service model is shown in Fig. 3.

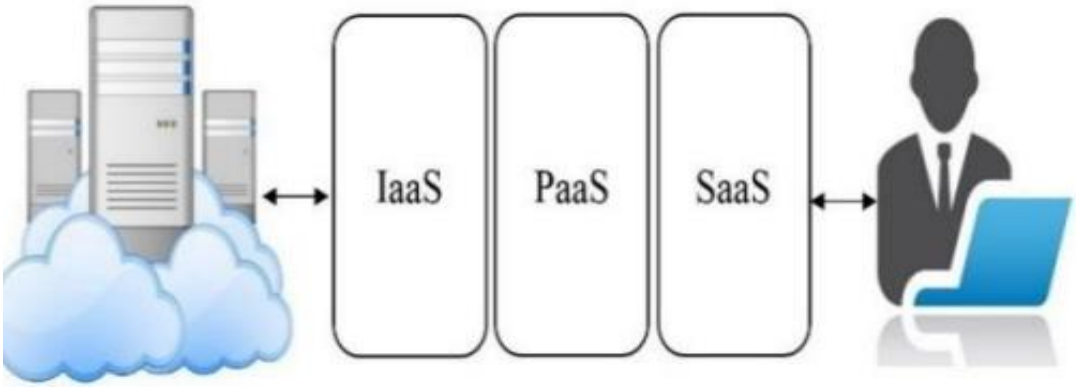

Fig. 3: Illustrates the Cloud Service Models

37.1.3. **Cloud Security***:*

Cloud security is a collection of control-based rules, compliance, and technologies that are used to secure cloud-based applications, data, and infrastructure. As more companies utilize the cloud for operational data, it has become increasingly important to contract for appropriate security and potentially susceptible regions. When it comes to shared resources, access control, privacy, and identity management, cloud computing security is a significant issue. The following are some of the issues raised:

- Data stored in the cloud may be improperly changed or deleted (unintentionally lost) by the service provider.
- Cloud providers, workers, and contractors may purposefully expose data stored in the cloud.
- In the cloud, resources are usually shared among many tenants, each of whom may be attacked.
- Data on the public network may be accessible through unsecured APIs and protocols.

However, when data is transferred to the cloud, data security becomes a challenge. The following are some of the security issues discussed in this section:

- **Cloud Storage Security:**

The popularity and acceptance of cloud storage is growing, posing a slew of security issues for both cloud providers and consumers. When utilizing file-sharing apps and cloud storage, IT professionals caution that all technologies, whether virtual or real, come with inherent dangers. Customers that keep their data in the cloud no longer own it since it is transferred via a third party, which implies that data privacy settings are beyond the control of service providers or businesses. Customers must verify that the cloud service is of high quality and that their data is

secure. Data leakage, BYOD (Bring Your Own Data), spying, cloud credentials, and key management are all security issues with storage[9].

- **Cloud Infrastructure Security:**

Cloud computing enables a dispersed workforce and offers many advantages to consumers, but it is critical to understand how to run the cloud infrastructure, which guarantees and verifies secure service deployment, data storage, communication, and safe operation via administration. Concerns about privacy, security, and dependability have surfaced as possible roadblocks with the increasing use of cloud services. At the application, host, and network levels, information security experts often establish the security guideline, rules, and practice of the organization's cloud architecture.

- **Software Security:**

Throughout their whole life cycle, the cloud provider needed to secure their apps or software from internal and external threads, from design to production. Instead of adding additional risk and posing difficulties for customers and cloud providers, it is critical to establish the security process and rules for the software that allows the company. Bugs, design faults, buffer overflow, and error handling agreements may all be used to help or hurt software security.

- **Cloud Network Security:**

It is the duty of a cloud service provider to allow only legitimate network communication and to prevent any harmful activity. The internal network infrastructure used by cloud providers to link cloud VMs to the provider network, such as access routers and switches, is not shared[10]. Internal network assaults, such as data leakage, illegal alteration, and denial of service or availability, are of concern to the client. Because the attacker may lawfully authorize from another section of the network, network security concerns both internal and external assaults. Attacks may occur on either a real or virtual network.

37.1.4. Security Challenges in Cloud Computing:

Cloud computing apps use the internet or an internal network to operate in cloud computing infrastructures. Customers verify the company's capabilities that it delivers the necessary services reliably and correctly, which is the notion of confidence in the organization. Trust in the cloud computing environment is dependent on the cloud deployment models chosen, in which applications are delegated and outsourced to the owner's management. In the conventional architecture, trust necessitated an efficient and effective security strategy that handled the functional limitations and flows between them. External systems get access to the restrictions that attack the programs that govern or provide access to consumer data. The community or public clouds assigned control to the entity that controlled the cloud infrastructure in cloud deployment models. The following are some of the security issues that cloud computing infrastructure may face:

- Integrity
- Confidentiality
- Availability
- Trusted Third Party (TTP)

37.1.5. Analysis:

This section covers the proposed security solution for the difficulties encountered in the adoption of cloud computing environments that encourage consumers to release security burdens by relying on a third party. Many cloud providers and consumers have expressed worries about

trust, security, and privacy, according to this research. The use of security methods in the cloud to ensure the integrity, confidentiality, and availability of data or systems, as well as to alter the relationship between the cloud provider and clients. To prevent unwanted access to shared resources, a reliable access control architecture is required. To enable safe communication, trust must operate at each tier of the cloud service models (IaaS, SaaS, PaaS), and it must guarantee security at the technological, legal, procedural, and operational levels. A trust certificate acts as electronic authentication and establishes an entity's credentials, identity, and obligations. TTP provides the necessary trust by ensuring the identification of communication parties or organizations and checking for compliance with stringent rules and criteria. The end user must use an electronic certificate to authenticate with the cloud service and to validate the access permissions to use the specific resources. Because the cloud architecture assures or protects the security of encrypting exchange data by combining the personal digital certificate with the service provider certificate (IaaS or PaaS), the secure SSL connection is established.

38. CONCLUSION

Cloud computing is a new technology that offers many advantages to consumers, organizations, and businesses. However, despite its many benefits, cloud adoption poses a number of security concerns. We went through cloud computing architecture in depth, including deployment methods, service models, cloud components, and cloud security. This study aimed to demonstrate a variety of security problems, threats, assaults, and vulnerabilities in systems or data during cloud transfer. The security threat countermeasures will aid businesses in continuing their cost-benefit analysis and encouraging them to migrate to the cloud. We addressed the general architectural concepts of cloud computing environments in this article, which arise from the need to keep track of important threads and vulnerabilities. Cloud computing security necessitates a basic point of view based on reducing security and trust to the TTP. The majority of the highlighted risks may be addressed with cloud computing using a mix of SSO, LDAP, and PKI to deal with the authenticity, availability, integrity, and secrecy of communication or data. This study may be expanded upon in the future to enhance the quality and availability of services, which will entice consumers to cloud computing deployments and increase customer confidence in TTP. In addition, cloud computing services that meet security needs include creating a framework for a comprehensive security and privacy trust assessment management system.

TRENDS IN CENTRAL ASIA: HEALTH RISKS FROM LARGE-SCALE WATER POLLUTION

Ms. Namrata Arya*

*SBAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: namrata.sobas@sanskriti.edu.in

ABSTRACT

At basin sizes, health-risk evaluations are hampered by a lack of data on the pollution state of geographically vast water systems. We show that agricultural and industrial pollutants in groundwater–surface water systems of the Aral Sea Drainage Basin (covering the main part of Central Asia) produce cumulative health hazards above guideline values in downstream surface waters, due to high concentrations of copper, arsenic, nitrite, and to a lesser extent dichlorod in downstream surface waters, using a recipient measurement approach in a terminal water body (DDT). We also conduct trend studies of these high-impact pollutants' upstream spatial–temporal distribution, examining prominent large-scale spreading processes. The ratio of parent DDT to its breakdown products indicated that discharges or depositions into surface waters were likely recent or continuing. Copper concentrations in river water rise in the spring following thawing and snow melt. The high geographical variability of arsenic contents in river water may be due to its presence in adjacent agricultural areas' top soil. Groundwater's were shown to be linked with much greater health hazards than surface waters. If the downstream population is forced to convert to groundwater-based drinking water sources due to a lack of surface water, health concerns may skyrocket. Due to continuing irrigation development and climate change, arid areas are particularly susceptible to this issue.

1. INTRODUCTION

Contaminants may be transported and spread from spatially restricted industrial or mining sites to large downstream regions via groundwater and surface waters, which are important parts of the continental water cycle. This is on top of the spread of more dispersed pollution, such as pesticides sprayed over agricultural areas. Man-made pollution has degraded the world's water resources to the point that they can no longer be restored to their original state. Health-risk evaluations and ecological impact assessments are useful tools for determining tolerable pollution levels and remediation target levels. For site-specific customization of successful remediation techniques, it's also necessary to consider how downstream pollution levels may vary in response to various feasible upstream remediation strategies, such as source removal,

land use changes, and various water treatments[1]. In addition, climate and other changes in the environment may have an impact on pollutant dispersal. As a result, remediation evaluations must be based on a scientific knowledge of large-scale dynamic flow and transport mechanisms. The lack of clear field datasets and syntheses of large-scale contaminant spreading that can be used for independent testing of various predictive models has hampered current scientific understanding. Observed changes must be significant enough to distinguish themselves from random variations induced by weather and geological variability, .The deepening environmental, health, and socioeconomic crisis in Central Asia (traditionally defined as the former Soviet Union states of Uzbekistan, Turkmenistan, Tajikistan, and Kyrgyzstan), which coincides to a large extent with the extensive Aral Sea Drainage Basin (ASDB), provides an example of severe human-induced changes in the continental cycling of water and dissolved substances . The problem is mostly due to the overexploitation of water resources in the lower desert area of ASDB during the Soviet period, which was exacerbated by massive irrigation projects. Overexploitation has resulted in a significant reduction in river flow into the Aral Sea, causing its desiccation. Groundwater flows have not dropped as much as surface water flows in recent years, and they have therefore become more significant Organochlorine pesticides and hazardous metals, including arsenic, have been found at high quantities in the ASDB's population's blood, milk, hair, and urine). Compared to 1960, before the ecological decline, maternal and infant mortality, child growth and puberty delays, liver and digestive system disorders, allergic problems, and diseases related to bacteriological status of water and soils have all increased significantly in this region Muntean et al. discovered that locally produced animal foodstuffs offer a significant exposure route for persistent organic pollutants in Karakalpakstan, Uzbekistan. Furthermore, in the lower ASDB, drinking untreated local water is widespread. Only 20 to 30 percent of the rural population in Karakalpakstan, for example, has access to piped water, while 25% of the population gets its water from irrigation canals[2]. It's possible that pollution exposure via drinking water contributes significantly to major health issues. Nitrogen compounds, copper, lead, chromium, and uranium, for example, have been reported to exceed World Health Organization (WHO) drinking water regulations in groundwaters and surface waters of the drainage basin We look at the health risks associated with the water-borne, basin-scale spread of a variety of persistent pollutants, such as pesticides and hazardous metals. The geographical coverage of surface water and groundwater monitoring sites becomes restricted when such vast scales are taken into account. Not to mention that comprehensive measurements of the groundwater system are difficult to come by. This problem is solved by interpreting new measurements in the downstream reservoir, which has effectively replaced the Aral Sea as a terminal water body and main recipient of pollutants from the ASDB's major groundwater–surface water systems due to severe water scarcity over the last decade. We identify the most dangerous pollutants from this hydrological focal point (in terms of human health) and synthesize data on their distribution in upstream water systems of the ASDB's biggest sub-basin, the Amu Darya drainage basin. We look at disparities between various hydrological systems (river water, reservoir water, and groundwater) as well as geographical and temporal patterns along hydrological routes. The research aims to uncover large-scale impacts of physical and chemical mechanisms that control the spread of persistent hazardous pollutants. Figure 1 shows The Aral Sea drainage basin (black solid line) with the Amu Darya river delta (dotted line) south of the sea, in which Mejdurechye Reservoir is located. Location of sampling sites for surface water and groundwater, main irrigated areas[3].

Figure 1: Shows The Aral Sea Drainage Basin (Black Solid Line) With The Amu Darya River Delta (Dotted Line) South Of The Sea, In Which Mejdurechye Reservoir Is Located. Location Of Sampling Sites For Surface Water And Groundwater, Main Irrigated Areas.

2. DISCUSSION:

2.1. Application:

The HFs for nitrate and nitrite in river water were below one and did not suggest a health concern, while the HF for nitrite in Nukus drainage water was close to three, indicating a health risk. In addition, the Mejdurechye reservoir water has considerably higher nitrite HFs (near to 4; Fig. 3a, right side) than the Amu Darya's upstream river waters. In the lower Amu Darya drainage basin's tested river and reservoir waters, the HFs for fluoride, arsenic, mercury, and copper were all less than one. Fluoride (HF= 0.4) and copper (HF= 0.2) in the Mejdurechye reservoir water had the highest HFs in the river-reservoir system. The arsenic HF in the Mejdurechye reservoir was likewise somewhat higher than in upstream river waters. Copper is the only one of the four chemicals listed in that has allegedly been measured in groundwater. Copper HFs in groundwater are two orders of magnitude greater than in river water and one order of magnitude higher than in reservoir water, according to the findings .When compared to the standard deviation values in [4], the temporal and geographical fluctuations of copper HFs in the river water of the Amu Darya delta are considerably lower, indicating that there is a systematic difference between copper HFs in groundwater and river water. The copper HFs in groundwater rise along the groundwater flow direction from Chalish to Dusenbay. Chromium, lead, manganese, and nickel concentrations in THC reservoir waters and upstream river water at Darganata are hazardously high, (left side), with HFs ranging from 1 to 5. If the higher US EPA guideline value is applied, HFs for chromium in reservoir waters are lower than 1. The choice of reference concentration levels for this chemical is the sole factor that influences whether the HF value surpasses 1. In particular, HFs for chromium (up to 280) and lead (up to 65) in groundwater samples from Chalish, Yangibazar, Dusenbay, and Buzkala[5]. The mean HFs for chromium and lead at river measuring sites between the THC and the Mejdurechye reservoir are approximately four orders of magnitude higher than these groundwater values. Furthermore, while we plot results from only four of the 14 groundwater sampling locations of Froebrich et al. in illustration purposes, the other ten sampling locations (in the Amu Darya delta within 45 km of the Amu Darya River) had similarly high groundwater HFs for chromium and lead (intervals of 120–280 and 20–70, respectively) [6].The four recent (2007–2008) monitoring sessions in the Amu Darya river basin's final surface water receiver of water-borne pollution, the Mejdurechye reservoir, revealed that cadmium and nitrite concentrations sometimes surpassed WHO's health-risk based guideline levels (Table S1). Copper, fluoride, -HCH, and arsenic concentrations were

slightly below their respective guideline levels, whereas nitrate, mercury, lead, and chromium concentrations were much lower. DDT and its degradation products were also detected for the first time since at least 2002 during the 2007–2008 campaigns. In the two 2007 campaigns, the CHF for the Mejdurechye reservoir, which expresses the cumulative harmful effects of the tested chemicals, was about 1, 0.03 in May 2008, and 9 in July 2008. On various measurement occasions, different combinations of chemicals contributed to high CHFs (i.e., CHF1): in July 2007, copper, fluoride, and arsenic dominated, while in October 2007, nitrite, fluoride, and copper dominated, and in July 2008, cadmium and nitrite dominated (see further Table S1 in Supplementary information for detailed Mejdurechye measurement results). When calculating CHFs, the WHO long-term exposure reference concentration for nitrite was utilized.Monthly measurement data from the stations Termez (Te), Tuyamuyn (Tu), Nukus (Nu), and Kziljar (Kz) located along an extensive upstream stretch of the Amu Darya river were available for four of the top five substances contributing to the Mejdurechye CHFs in 2007 and 2008 (arsenic, copper, fluoride, and nitrite).illustrates the proportion of substantially difference ensemble mean HF values across groups when categorizing data by location, year , and season of measurement for these four high HF drugs. In four of these six instances, the difference in mean arsenic HFs between sites Te–Tu, Te–Nu, Te–Kz, Tu–Nu, Tu–Kz, and Nu–Kz was determined to be statistically significant. Te–Tu and Nu–Kz were the only two location pairings that did not have significantly different mean values. The underlying ensemble mean HFs and standard deviation values for Te, Tu, Nu, and Kz help to explain this finding. The picture depicts a significant range overlap (mean one standard deviation) between the upstream Te and Tu stations, as well as the downstream Nu and Kz stations, as well as a lack of overlap between all other potential station combinations, yielding the statistical result. As a result, there is a noticeable difference in mean arsenic HFs upstream and downstream. The spatial variation of nitrite HFs is also significant. also indicates that arsenic and nitrite HFs have large geographical variability when compared to yearly and seasonal changes[7].

2.2. Advantage:

The ASDB is a 1,874,000-square-kilometer endorheic basin that includes two major rivers that flow into the Aral Sea: the 2400-kilometer-long Amu Darya River and the 2500-kilometer-long Syr Darya River. The Amu Darya River flow accounts for a significant portion (about 70%) of the ASDB's renewable water resources. The primary source of river discharge is meltwater from the Pamir Mountains' snow and glaciers, which produces flow maxima between April and September. Before the irrigation system's large-scale development, the average Amu Darya discharge was 78 km3 per year1. Because the Amu Darya River basin comprises the majority of the ASDB's irrigated lands, river discharge currently fluctuates between 0 and 1 km3 year1.Toxic chemicals have been dispersed over agricultural areas, including Fig. 1, as a result of widespread usage of fertilizers, insecticides, and herbicides. Mejdurechye Reservoir is situated in the Aral Sea drainage basin (black solid line) with the Amu Darya River delta (dotted line) south of the sea. The location of surface water and groundwater sample locations, major irrigated regions (outlined in grey; Global Map of Irrigation Areas, Siebert et al., 2005), and the Aral Sea extent in 2005 (filled blue) and 1960 are shown. (The reader is directed to the online version of this article for interpretation of the color references in this figure legend) DDT, -hexachlorocyclohexane (-HCH), arsenic, and copper are all examples of chlorodiphenyltrichloroethane (DDT). Surplus irrigation water evaporates or returns to rivers, resulting in a build-up of agrochemicals and salt in the rivers downstream. Furthermore, substantial mineral reserves were discovered inside the ASDB during the Soviet period. Cadmium, copper, lead, and uranium, for example, are metals obtained from Uzbekistan's current mining sector (Clark and Naito, 1998)[8]. Acid mine drainage, which often includes high metal concentrations, particularly increased arsenic concentrations, is a major pollution source in

ASDB as a result of the well-developed mining sector Because of its physical position further downstream in the basin, the Amu Darya river delta receives water-borne pollution fluxes from the major portion of ASDB. The delta is located in a semi-arid climate. Summer temperatures vary from 45°C to 30°C, while winter temperatures range from 30°C to 45°C. Annual precipitation averages 133 millimetres, and potential evaporation ranges from 1200 to 1600 mm. As a result, it is completely reliant on runoff from upstream regions flowing via rivers and canals. It therefore has features similar to the Nile delta in Egypt and the Eufrat–Tigris marshes in Iraq in terms of water balance and vulnerability. The Amu Darya delta and related irrigation canal networks encompass almost twice the size of the Nile delta, with a total area of 40,000 km2. Since approximately a decade, the Amu Darya River has run dry before ever reaching the Aral Sea's old coastline. The Mejdurechye reservoir, with an area of approximately 180 km2 and a maximum depth of 4 m (for a more comprehensive description, see the Supplementary material), is one of the biggest water bodies in the delta and has effectively become a new delta terminal water body[9].

2.3. Working:

We calculate health hazards using hazard factors (HFs), which are calculated by dividing observed concentration levels by a reference concentration, with HFs greater than 1 indicating possible health concerns. The reference concentration is a substance-specific concentration below which there is a very minimal probability of harmful health consequences if a lifetime consumption of water at the reference concentration is consumed The HF quantifications presented here are based on WHO drinking water guideline levels. Due to quantification uncertainties and different assumptions regarding, for example, body weight (WHO assumes 60 kg and U.S. EPA assumes 70 kg) and relative source contribution for substances that are primarily likely to come from food, the US Environmental Protection Agency's (US EPA, 2006) guideline values may differ from WHO values (WHO assumes 10 percent and U.S. EPA assumes 20 percent). The two standards vary by a factor of two or more for chromium, fluoride, mercury, and -HCH. The effect of the HF discrepancies on interpretations and findings is then reported. The addition of substance-specific HFs to a mixture may be used to quantify the health risks of multiple co-existing dissolved pollutants. In the absence of more specific data on interactions between the components of the investigated combination, this gives a cumulative hazard factor (CHF=HF), which, with its presumed additive toxic effects, offers a meaningful first-order estimate of aggregated toxicity. CHFs were computed for the combination of chemicals detected during each of the four sample sessions conducted in the Mejdurechye reservoir in 2007 and 2008. The period between the Soviet Union's DDT prohibition and the measurement campaigns in 2007–2008 is longer than DDT's half-life in soil. If variations in transport characteristics between DDT, DDD, and DDE were ignored (e.g., assuming equal retardation), sources of old DDT from before the ban would produce rD b1 in water that is much lower than observed. As a consequence, assuming this simplifying assumption is correct, the observed DDT cannot be due to subsurface movement of ancient DDT. The simplifying assumption can be relaxed by taking into account differences in retardation between DDT and its degradation products, with the partition coefficient Kd for DDT (log Kd= 4.8) being higher than for DDE (log Kd= 2.7) and DDD (log Kd= 2.9) (Walters and Aitken, 2001), implying higher retardation and slower transport of DDT than for DDE and DDD.These retardation differences, in comparison to the equal retardation case, may contribute to decreases in rD at downstream observation points, because low DDT concentrations would persist for longer due to its higher retardation. Whereas \sa) \sb) \sc)Mean HFs for nitrite and nitrate in drainage and river water, b) fluoride, arsenic, mercury, and copper in groundwater, reservoir, and river water, and c) cadmium, chromium, manganese, nickel, and lead in groundwater, reservoir, and river water. The locations of the reservoir water samples are highlighted. Samples with concentrations below

the detection limits (DL) and thus low HFs are indicated by values below the horizontal solid lines. The locations are categorized from left to right in the figure based on upstream to downstream mean surface waters and groundwater flows. Abbreviations: THC stands for Tuyamuyn Hydrological Complex Reservoir, while Mejdu stands for Mejdurechye Reservoir. While this logic is valid in many instances, there are certain outliers in which variations in retardation may lead to increases in rD. However, such events (which can mask the true age of old spills by making them appear more recent) are limited in space and/or time; for more information, see the Supplementary information. The Mejdurechye reservoir, in particular, receives pollutants from large upstream areas and has been monitored for a long time. Overall; it seems that ancient DDT is unlikely to account for the elevated rD observed in the Mejdurechye reservoir. Another possible reason is that the DDT leak was just recently discovered. DDT has a short half-life in surface water, so it couldn't have been in contact with it for very long before being detected in the Mejdurechye reservoir. This narrows the range of possible DDT sources to illegally stored stockpiles, recent storage site leakage, and atmospheric deposition. Similarly high rD-values have been found in South China's Pearl River Delta waters, suggesting continued DDT usage after China's 1983 prohibition. Copper pollution is mostly found at the ground surface or in the near-surface environment, according to the ASDB. Copper mining tailings and agricultural areas, where fertilizers (such as copper sulphate) and insecticides are utilized, are two potential sources. Copper HFs peak in the Amu Darya's most downstream river gauging station (the Kziljar station; near to the Mejdurechye reservoir entrance) during the spring, when precipitation is high. The statistically significant connection between season and copper content is mainly due to increased copper concentrations in March. Copper may build in higher soil layers during dry periods and then mobilize during early high-precipitation events of the growing season as a consequence of leaching and/or soil erosion, according to one possible explanation. For example, Zhang et al. suggested this process as a possible explanation for dissolved copper peaks in drainage water from agricultural areas in St. Lucie County, Florida. It may also explain certain findings made by Bordalo et al. in Thailand's Bangpakong River. Lower winter temperatures (below 0 °C), more extensive irrigation, and an arid environment with precipitation events mostly confined to winter and early spring set the lower Amu Darya region apart from the research regions of Zhang et al. and Bordalo et al. The current findings indicate that copper concentrations peak after thawing and snow melt, and then decrease throughout the summer season, despite significant water re-routing to irrigate areas. The lower Amu Darya river's nitrite concentrations were similarly greater in the spring than in the summer; co variations between copper and nitrogen compounds also occur under various environmental circumstances, as documented by Zhang et al. and Bordalo et al. Natural arsenic has little effect on surface water systems unless there are geothermal sources. Our findings indicate that in the presence of human-made arsenic sources (from agriculture and potentially mining), arsenic may leach into surface waters to the point where it contributes significantly to CHFs in drinking water. Previous studies on arsenic leaching from cotton fields have also shown that vertical arsenic migration is very limited even under irrigation, so leaching into surface water systems is likely to be the main transport pathway for anthropogenic arsenic (as opposed to natural arsenic). Smedley and Kinniburgh found geographically restricted arsenic contamination in surface waters near recognized superficial sources, which is consistent with the significant spatial variability of arsenic contents in river water along the Amu Darya (mining tailings). As a result, high arsenic levels in downstream ASDB river water stations may indicate its presence in adjacent agricultural areas' top soil[10].

3. CONCLUSION:

The cumulative health hazard factor (CHF) of the examined pollutants ranges from negligible to roughly 10 depending on the time and place of drinking water consumption. Copper, lead,

nickel, manganese, and chromium contents in the Amu Darya delta were found to be higher than WHO drinking water guideline levels. Although average cadmium readings were below the recommended limit, specific testing occasions surpassed it. The recognized negative health consequences of an excessive consumption of these pollutants. As a result, it's fair to believe that poor drinking water quality has had a role in the situation. Because low-risk surface waters still persist (at least temporarily) in certain parts of the Amu Darya delta, it's possible that water control schedules may be tweaked to improve water quality in terms of aggregated toxicity at key drinking water intake sites. The Amu Darya delta's groundwater in formations that (from a hydrogeological standpoint) can support larger-scale drinking water supply contain substance concentrations that are orders of magnitude higher than WHO drinking water guideline values, in contrast to relatively low-risk surface water systems. This means that consuming water derived from groundwater poses significant health hazards, much more than those posed by surface water. Furthermore, as a result of a surface water scarcity that has already resulted in the desiccation of the Aral Sea, demands on switching from surface water-based drinking water supplies to groundwater-based supplies are strong in the Amu Darya delta. Current findings indicate that switching water supply systems (from surface water to groundwater) may result in a significant worsening of health hazards, in addition to potentially lowering groundwater levels owing to inadequate recharge. Due to continuing irrigation development in the upstream portion of the Amu Darya drainage basin and ongoing climate changes, the surface water scarcity is projected to worsen in the near future. Similarly, in many arid areas of the world, polluted groundwater may become the only remaining water source, as surface water discharges are expected to decrease globally in response to projected global irrigation increases and projected climatic changes.

ABSTRACT

People who suffer from serious mental illness often find it difficult to continue, and dropout rates are high. A client's perception that the therapy would fulfil his or her own particular objectives, the therapeutic relationship, and the accessibility of care are all variables that may affect treatment participation. As a result, we have found that recovery-led care is a helpful tool for examining techniques and approaches that encourage engagement with the person receiving support, with independence, empowerment, and respect as top priorities. Person controlling is a treatment approach that focuses on the individual's unique goals and circumstances, including shared decision-making. The use of personal care in mental health treatment models has shown to be effective. Historically, some groups of individuals, such as young adults experiencing their first episode of psychosis, those with complicated psychiatric and drug use issues, and homeless people, have been difficult to engage with. This research emphasizes these stigmatizations and shows how different evidence-based treatment methods have improved their outcomes. The emphasis of this research is focused on therapeutic approaches that may improve involvement. Therapy is complex and varied; nevertheless, providing services to individuals with serious mental illnesses necessitates the development of optimum recovery-oriented skills and attitudes.

KEYWORDS: *Health, Mental Illness, Social, Stigma, Treatment.*

1. INTRODUCTION

Mental illness, sometimes referred to as mental health problems, refers to a variety of illnesses of psychological health that impact your mood, thought and conducts. For insance, depression, anxious disorders, schizophrenia, food problems and addictive behaviour. Many people occasionally experience mental health issues. However, a mental health problem is becoming a mental disease whenever continuous indications as well as sensations often create stress and influence your functioning. Mental illness can miserably lead to issues, such as at school or job, in your daily life[1]. In many situations, medication and speech treatment can also be used to control symptoms (psychotherapy).

Mental stigma is when someone looks down on you because of a certain feature or quality (such as cultural background, a mental illness). It is discrimination if someone treats you in a bad way due to your mental condition. Stigma occurs when a person defines someone by his disease and

not as a person. For example, they may be labelled 'psychotic' instead of 'psychotic.'Social stigma and prejudice can exacerbate their problems for persons with mental health concerns and make it more difficult to rehabilitate.

This might drive the individual to resist receiving treatment because of fear of stigma.Persons with severe mental illness typically have difficulty continuing therapy and a stopping therapy is all too prevalent. Because various variables help to preserve someone's commitment to therapy and readiness to quit, it is a difficult to identify important components for improving engagement.

Disengagement may be connected to problems of utility, attitudes (people feel that therapy does not work), distrust, or practical reasons or problems (treatment may be difficult to get to, difficult to schedule).There is no one method, because involvement is taking place in the context of a unique personality, social as well as living conditions of an individual and the weight of symptoms. Approaches that address any and almost all of the alleged barriers can be utilised to increase treatment engagement most effectively. In this study, we highlight some practical and conceptual advances in the treatment of mental health that have demonstrated an increased commitment to mental health care.

In a specific social setting, stigmatised persons have (or are thought to possess) some characterization or quality which transmits a societal identity. Simply said, stigma is a negative manner of judgement which develops on a societal level and which is not particular to a person linked with some features and conditions. When society accepts a certain, generally unfavourable, image with subtle features, it is called a stereotype in a given set of people. The stigma is a complicated political and socially influential phenomenon.

1.1 Prevalence of Mental Illness Related Stigma:

Mentally ill people are, according to the World Health Organization, frequently exposed to violations of human rights, stigma and discrimination. Several researchers have found a link between drug use, prostitution, and criminality between common conceptions of mental health. Other research has indicated that there is a less unfortunate public response to mental illnesses, with a significant percentage of those disabled. This may affect the right of people with mental illness to secure living, medical care and employment.

It is not simply stigma and unfavourable convictions that affect the public.Healthcare professionals show some undesirable mental health attitudes. In many areas of healthcare, stigma and discrimination may be found. Psychiatric disease might get less funding, lower standards and a broadly based harmful society.Pre-based stereotypic ideas, discriminatory behaviours and negative attitudes when transferring to healthcare might influence patient interaction. Patients have been said to devalued, rejected, and dehumanised by many health workers.

Healthcare professionals cannot unconsciously express unfavourable sentiments about people with mental health problems. Except for decision making, lack of severe symptoms, lack of physical and mental know-how and paternalistic or condescending behaviour[2]. A survey of Turkish physical therapists using ideas on mental illness indicated that Turkish physiotherapy students had moderate positive attitudes. Students experiencing mental illness relations or psychiatrists as well as psychotherapists were better in grades.

1.2 Impact of Stigma on People with Mental Illness

Mentally ill persons confront both the difficulty of the condition and the stereotype and criticism. Public stigma is not just a kind of stigma, but also a kind of stigma. Public stigma is also involved. Self-stigma is a barrier to personal growth and can challenge the achievement of a positive position in personal and professional life. Between stigmatised persons there were

higher cortisol levels and depression[3]. Those who stigmatise are disgusted. Stigma has a different dimension in healthcare. Because mental health is linked to less productive views, professionals in medicine cannot seek assistance and fear their colleagues' judgements with an elevated suicide risk when needed. In a different way, some authors have found that stigma has a positive influence on mentally ill persons. While some people may experience a danger, others may be energetic and more driven in therapy.

Techniques and instruments for enhancing involvement in the rehabilitation-oriented care framework are beneficial for viewing. This recovery reflects a change of mind set and of professional approach that has developed over the last several decades, with a report from the proposing recovery-oriented, consumer- and family-driven mental healthcare[4]. The promotion of citizenship, organisational commitment, supporting personal objectives and a good working relationship5 are four elements of recovery-led practise. Four dimensions include the following techniques are all potential strategies for care providers to improve their participation in people with significant mental illness if they adopt a recovery-oriented position.The stated priority of autonomy, empowerment and respecting the individual receiving treatment are a very significant characteristic of recovery-oriented care. This study thus describes variables that might improve the experience as well as hope of recuperation of a client.

1.3 Stigma Around Mental Illness

Organizational discrimination has also been highlighted as a significant problem for mental health. Stigmatizing views can prevent people with a mental condition from seeking assistance, prevent them from successfully reintegrating themselves into society and enhance their psychological problems. Several stigma studies have focused on the overall stigmatisation of ideas and behaviours. However, stigma towards psychiatric consumers is not an unusual issue among professionals[5]. Professionals typically tend to reflect the public's negative sentiments about more explicit elements of the stigmatisation process.

These are the fundamental aspects of social stigma, such as stereotyping and social remoteness because preventing damage to, upsetting, and disrupting human lives. It is vital to include mental health professionals as a major target group in anti-stigma initiatives since their attitudes are not that different from unfavourable general views of mental illness.Professional mental health specialists are specially trained in the treatment of mental illness and obviously more in contact.

As a group, it would be reasonable for them to think that in relation to the laity, nonmedical professionals and / or medical students, their views towards people with mental diseases have been less stigmatising. This does not seem to be the case, however and the stereotypes of the public are reflective, as indicated above. Knowledge of the disease and ongoing interaction therefore appears not to be sufficient to address the stigmatic issue.

A number of solutions have been offered to address the question of stigmatisation by experts in mental health.These include the improvement of vocational training, quality assurance and prevention of burnouts through regular monitoring. Neither has been tested in particular so yet, though. Moreover, there is an insufficient awareness of the fundamental components of training which should assist to reduce these stigmatic views.This research examines whether it would be helpful in decreasing stigma among professionals in mental health for the mentally ill, focusing on the fundamental questions of stigma and discrimination (e.g., psychoanalystsas well as psychiatric inhabitants).

1.4 Attitudes And Interpersonal Focus:

1.4.1 The Therapeutic Alliance:

The therapeutic alliance is a description of the connection between physiotherapists and their patients, sometimes called the working alliance. The therapeutic relationship can also have an influence on treatment results as an important element of the therapeutic process.The therapist then attempts to give a patient-centred treatment by creating a therapeutic alliance whereby the therapist is regarded as a helper for the patient's aims rather than an entity[2].The significance not just of delivering patient-centred treatment, but also of other medical occupations, in physiotherapy. The aim is to encourage the patient to become more involved in their therapy in a collaborative and active recovery approach.

The therapists are able to strive to treat the psychological components of pain, frequently ignored in typical unidirectional patient-therapist encounters, by building a strong therapeutic relationship and promoting patient engagement. This is especially essential, as current study has shown that the improvement of patient results cannot be fully taken into account in physical treatment alone.The clinician's recovery guidance, lower reported self-stigmatism, and higher degrees of insight included schizophrenia and schizoaffective illness, independent therapeutic alliance predictions. Interestingly, the quality of alliancewas not linked to the severity of clinical symptoms, the type of attachment, age and length of the therapy. Recovery-oriented efforts from a physician might improve the relationship.

1.4.2 Person-Cantered Care:

The concept of person-cantered care is becoming increasingly common in the changing health care landscape. Person-cantered care has no single, operationalized definition or standard of measurement. In the context of mental health services, we find particularly compelling the following description of person-centric care as well as an appropriate foundation to evaluate:

It is the concerted effort to incorporate an individual’s own culture, background and immediate goals into treatmentplanning.Engagement can be strengthened via mental health therapies that include aspects that meet current needs of an individual. Housing and finance, for instance, are two possible causes of major stress that may affect the well-being of someone[6]. Addressing these obstacles as particular clinical care components might assist to increase participation.

If someone is financially safe and accommodated, he/she may have fewer specific hurdles to therapy. A more indirect, larger effect of addressing these healthcare components might be for the receiver to feel assisted and increase their trust in the system, develop alliances and serve as the basis for future treatment efforts.The same decision-making process may be seen as a single method to caring for people. Comparative decision-making is a joint, dynamic interactive process between two equally involved participants, in contrast to more authoritative healthcare delivery patterns.

In this paradigm, both the physician and the patient participate in an information exchange that leads to an agreed treatment decision[7]. This approach to therapeutic care has been apparent during the past decade, albeit many of the research investigating its effectiveness have been conducted in non-psychiatric groups.While several studies have shown that common strategic planning for people suffering from severe mental illnesses is helpful, caregivers may fear that the ability of patients to make a choice is hindered and may hence be less inclined to employ shared decision-making in this group[8].

Because the participants' impression because their objectives, wishes as well as circumstances are taken into account is one recurrent theme emerging from effective engagement analysis, it is reasonable that a much more shared decision-making approach might increase care commitment. Self-efficacy itself has also been linked to enhanced therapeutic results[9]. It may not be the actual decision point but the patient and the provider process that is the most significant result of

the shared decision-making process. An open, inquisitive as well as non-judgmental atmosphere provides confidence and improves therapy commitment optimally.

Their engagement in decision-making is to be high in both mental and no psychiatric healthcare. Understanding this, can influence decision-making improve therapy and development? There has been a definite relationship between treatment satisfaction and the degree to those, which individuals would like to participate in the decision-making process.Those who felt obliged to undergo treatment (lower-perceived justice, poorer pharmaceutical experiences) or had greater degrees of treatment dissatisfaction have said they wanted to be more involved[9]. By contrast, the desire to engage in medicinal decisions was reduced for individuals persuaded they need medicines and indicated great pleasure.

The studywith severe mental illness shows that all of those functioning earning pay, college and higher education, having diagnoses and having an inadequate therapeutic connection with such a therapist were more inclined to take part in joint decision-making. The study showed that decision-making preferences vary over time and an ongoing assessment of the position of the patient is an important part of excellent clinical treatment.

The adoption of collaborative decision making in therapeutic settings can be assisted by web-based and technological technologies. One research investigated the usefulness of integrating a computer-based tool in the waiting room of a community clinic for common decisions, in which people with severe mental illness had received treatment. Before doctor's appointments, participants utilised this tool to produce a written document detailing any decisional disagreements with the doctor[8].This helped participants to explain their personal difficulties, to enable them to discuss tough themes and to organise their thoughts. The authorhas created and are largely recognised by both patient and physician, additional web as well as computerized judgement aids.

1.4.3 Substance Use And Serious Mental Illness

Those with severe mental health are more prone to use substances than those with no such diseases, with some research that indicate that 50% to 60% of schizophrenias have a comorbid problem with substance use. It is generally recognised that it is harder for individuals who are suffering from significant mental illness and substance use than without them, and standard therapies have failed to engage this demographic effectively[10]. Drug addiction is actually one of the most important aspects in the patients with mental health, which is not initiated or engaged.This difficulty is associated with several downstream consequences, such as rehearsal often, high symptom severity, psychosocial impairment and a Tran’s agency in prisons and other non-mental-health settings.

This difficulty has several downstream implications. The fragmentation of the care system is one reason why people with double diagnoses may be less involved in therapy.In the history of drug use treatment and psychiatric thermal programmes, various financing streams, training and philosophic approaches have been completely separated. This often prevents persons who have been diagnosed with dual diagnosis getting treatment from either program.

An individual seeking the treatment of "psychiatric" symptoms was notified first and vice versa. This sequence-based treatment strategy failed to take account of the interactive and cyclical character of these diseases as well as adding yet another barrier to care. 48. Integrated dual diagnostic therapy programmes emerged in the 90sand tried to respond to the fragmented treatment of people who had been diagnosed with two diagnoses. They highlighted outreach, integrity, a long-term view and a consistent approach and attitude.

Training in motivational approaches, cooperation, social assistance and a community supporter included several such programmes. The treatment for people with double-diagnosis is now

scientific proof and studies showed that the approach enhances diverse treatment benefit, including participation in treatment, possible substance use reductions, more unstable dwellings and more reductions in psychiatric hospitalisation and arrest. Some research suggest that the dual diagnosis is improved initially and ongoing, together with integrated treatment programmes, including assertive community treatment.

The elements found for enhancing participation include shared objectives, positive views that concentrate around medicines, continuing psychoeducation, collaboration on team care, and community outreach, among numerous treatment programmes that treat sub-stance illnesses and mental health problems.

2 DISCUSSION

While this study provides an insight into an intervention in contacting knowledge to reduce the stigma of mental illness and improve adolescence mental health literacy, limitations include self-report measures, low reliability of the results variable in our own voice measurement and incontestability in the analysis for intergroup contacts. Furthermore, we did not gather information on the use of psychological services to appreciate the generality of the results of studies.

Many innovative strategies are emerging to improve treatment engagement. As demonstrated in this review, engagement strategies focus on practical methods and tools, as well as on helping to change attitudes and overall approaches to treatment of people with mental illness. In order to implement these strategies to improve engagement, mental health providers, too, must feel engaged with the work they are doing. The new approaches call for open-mindedness and flexibility about a shifting structure and delivery of mental health care.

In addition, this study might be a moderating variable.The inability to audiotape may indicate low fidelity to the implementation strategy component involving audit and feedback. Wide variation occurred in clinician participation in training and consultation, as well as consumer recruitments. However, clinicians who were more engaged in the implementation strategy were more likely to report intended future use.

3 CONCLUSION

However, presumably, all mental health providers are in this field because they are dedicated to improving the well-being and health of those who suffer from mental illness, individual and systemic barriers may prevent providers from delivering treatment that optimally enhances participant engagement. The realities of working within the current mental health system include limited resources, limited time, and increasing oversight by managed care companies. Clinicians commonly cite these concerns as reasons why they are reluctant to change treatment services or take on amore recovery-oriented approach. In tandem, there are myriad attitudinal concerns about recovery-oriented treatment, including fear of increased risk, concern that only certain types of participants can be engaged in treatment, and an assumption that recovery-oriented services devalue professional skills.

It is clear that, in order to affect global change, these concerns must be addressed. Services can be streamlined to more efficiently utilize resources, relieving some of the existing pressures that psychiatrists face, and thus allowing them more time to engage in face-to-face, meaningful

clinical interactions. Making concerted efforts to address fears, stigma, mis-conceptions and practical constraints will help to transform our mental health system to improve initial and ongoing engagement.

This review is other areas to consider as ways to enhance treatment engagement include wellness and exercise, role of families – including siblings – in treatment engagement, and use of trauma-informed care to engage individuals with traumatic pasts. Future areas of research may explore issues related to training and implementation of engagement strategies in the context of a rapidly evolving mental health care landscape.

ABSTRACT

The article presents the work of the building in difficult soil conditions, building precipitation, measures to change the rigidity of the building, the main structural measures preventing uneven settlement of buildings and structures. The timing of construction can also affect the process of settlement of a building if its individual parts are erected at different times. The solution to the problem in such cases is to use lighter materials for the later fragments of the building. These can be brick or wood inserts between parts of the building made of reinforced concrete slabs.

KEYWORDS: *Construction, Industrial, Subsidence, Significantly, Individual*.

INTRODUCTION

When building on subsidence loess soils, on weak water-saturated clay and saline soils, as well as in other difficult soil conditions, the subsidence and subsidence of the foundations of industrial and civil buildings turn out to be much larger than allowed for this type of structure. For difficult soil conditions in the construction of residential and industrial buildings, the average settlement value is often less than the allowable value, but the difference in settlement between adjacent columns or panels is much higher than the allowable values.In this case, you can either significantly increase the area and depth of the foundation; in some cases, replace strip and free-standing foundations with pile foundations; to carry out work on strengthening the base soils; or to strengthen the structure of the structure so that it is normally operated at high precipitation and with large differences in the draft.

The experience of using constructive measures has shown that in most cases they can significantly reduce the construction time and reduce the cost of construction and installation work.

Constructive measures can be provided for in projects of newly built structures or applied directly during construction. For example, if during the construction of a building the soils were frozen and frost heaving processes were observed, and after thawing the soils became highly compressible and low-strength, the problem arises of how to construct buildings if the first floor has already been built. You can disassemble the constructed part of the building, remove the foundation cushions, remove the soft soil, fill it with sand and start building the building again. However, in some cases, it is possible not to disassemble the structure, but to arrange monolithic reinforced concrete belts at the level of the floors of a brick building, reinforce the brickwork in the walls and continue the construction of the structure. Constructive measures are also used to restore the design position of individual elements of a structure without stopping the operation of a building or structure. The experience of operating industrial buildings on weak water-saturated clay and sagging soils shows that, as a result of uneven settlement of columns of industrial buildings, it is often necessary to raise (straighten) crane runways, sites for special equipment, etc.

PURPOSE OF THE STUDY

To increase the rigidity of a building, such structural schemes are usually used that are not very sensitive to uneven precipitation. So, for example, instead of continuous multi-span beams, split single-span beams are used. The overall rigidity of the building also increases with the use of monolithic reinforced concrete foundations.

Prefabricated foundation blocks are not able to redistribute efforts, therefore, if necessary, to increase the rigidity of the structure, instead of prefabricated strip foundations, monolithic strip foundations are arranged, often with a large number of longitudinal working reinforcement. To further increase the rigidity of buildings, a foundation is made of crossed monolithic reinforced concrete foundation beams, and in some cases, a solid reinforced concrete slab under the entire building or within a part of the building bounded by sedimentary joints. It is also possible to use prefabricated monolithic foundations.

Monolithic and prefabricated-monolithic foundations are able to redistribute stresses in structures of structures that arise during uneven settlement of foundations.

The spatial stiffness of buildings increases significantly with the construction of closed reinforced concrete belts, which are laid continuously at the level of all floors along the capital walls. In cases where a significant increase in the rigidity of the building is not required, it is possible to install reinforced concrete belts at the level of the basement floor and at the floor level of the penultimate floor. Interfloor floors should be anchored in reinforced concrete belts, the size of which is established based on the calculation. Usually, reinforced concrete belts are set with a height of 15-40 cm based on structural considerations (the height of a reinforced concrete belt is taken equal to a multiple of the brick size), the width, as a rule, is taken half a brick less than the thickness of a brick wall. In the southern regions of our country, where there is no danger of freezing through the body of a reinforced concrete belt, the width of the belt is taken equal to the width of the wall. Brick buildings with reinforced concrete belts allow a settlement 3-5 times greater than panel or block buildings.

When designing and building multi-storey structures or structures of great length, sedimentary seams should be arranged, which should separate the multi-storey parts of the structure from each other and divide the structures into rigid blocks of small size and simple geometric shape. The distances between the sedimentary joints are taken such that the part of the building located

between the sedimentary joints has greater rigidity. Sedimentary joints should be arranged in structures of great length, taking into account the engineering and geological structure of the construction site.
Sedimentary seams are arranged in places where the thickness of the layer of weak water-saturated clay soils changes, in places where one type of soil is replaced by another with different deformative indicators. The part of the building separated by sedimentary seams must have an almost uniform settlement, and the settlement between adjacent sections of structures can differ significantly. The locations of the sedimentary joints are also established taking into account the internal layout of the building and the change in the rigidity of the structure along the length.

The distance between sedimentary seams in structures located on a layer of weak water-saturated clay soils is taken for brick buildings equal to 45-60 m, and for panel buildings - 20-45 m. Sedimentary seams can be removed along the length of the building at different distances.

In industrial structures, settlement joints are positioned in such a way as to highlight the part of the building with a heavier operating crane mode.

When carrying out constructive measures in industrial construction, it is necessary to provide for the creation of a stock in dimensions above the bridge cranes. This is due to the fact that the buildings of industrial workshops often have an uneven settlement, especially in those cases when they are located on weak water-saturated clay soils. At the same time, precipitation increases slowly over several years and decades. For normal operation of an industrial building with overhead cranes, it is necessary to periodically straighten the crane runways on those columns that had a draft.
As a result of the lifting of the crane runways, a situation often arises in which the top of the overhead crane touches the floor trusses. In this case, it is necessary to suspend the technological process and reconstruct the workshop. When designing industrial workshops with overhead cranes, it is also necessary to provide devices for quick straightening of crane runways. For particularly critical structures, special structures and devices are required for lifting individual columns or frames of industrial workshops, as well as foundations of highly accurate machine tools.

Foundations for individual supports of high masts of power transmission lines, masts for radio and television on a layer of weak water-saturated clay soils should be connected to each other using prefabricated or monolithic reinforced concrete beams. For such structures, it is best to design pile foundations with wide grillages. In this case, it is necessary to arrange a sand cushion with a thickness of at least 20 cm under the grillage. It is also possible to use screw anchor piles.

In the body of foundations for automatic lines, it is necessary to provide for the device of brackets or specially designed stops for the possibility of jacking up and restoring the design position of the foundation of this technological equipment, followed by concreting of the raised foundation.

CONCLUSIONS

The main constructive measure in the construction of residential five- and nine-story buildings is the use of reinforced concrete and metal belts. In this case, there is a certain overexpenditure of metal, but operating costs are significantly reduced.

Constructive measures can be assigned during the construction of buildings and structures, if, as a result of various meteorological influences, shrinkage of clay soils occurs, the destruction of weak soils at the base of the foundations as a result of improper pumping of water from the pit, with the dynamic effects of construction machines in the process of movement of mechanisms along the bottom of the pits, etc. Constructive measures should also be carried out if the

development of foundation pits within the same structure is carried out to different depths or different degrees of soil destruction are observed in the foundation of buildings. In addition, if during excavation it is established that the base of the foundations is composed of soils with different properties, or a diverse occurrence of various soils is observed in it, or separate layers of weak clay soils wedge out within the contour of the structure, or within a part of the structure between deformation seams, the rigidity of the structure should be increased by constructive measures.

INNOVATIVE ACTIVITIES OF STUDENTS IN THE EDUCATION SYSTEM OF THE REPUBLIC OF UZBEKISTAN

ABSTRACT

The work examines the issues of IWS and develops their specifics in the educational system. A promising stage in the implementation of independent work is a production workshop. At the same time, the teacher acts as a consultant and monitors the student's activities. To stimulate and constantly maintain students' interest in obtaining new knowledge, more attention should be paid to teaching them self-education system. Students must master the basic and individual specific constituent elements of the teacher's work: work with scientific, methodological and educational literature; present educational material, compose a system of differentiated exercises and manage it in the process of solving a problem; use the techniques of posing a question, formulate organizing and governing questions, as well as versions of the same question; quickly and adequately respond to the emerging educational situation; be able to control and evaluate knowledge, etc. Independent work of students is their activity in the learning process and in extracurricular time, carried out on the instructions of the teacher, under his guidance, but without his direct participation. Putting this feature as the basis for the classification, we subdivide it into five groups: the acquisition of new knowledge and the mastery of the skills to independently acquire knowledge; consolidation and refinement of knowledge; developing the ability to apply knowledge in solving educational and practical problems; the formation of skills and abilities of a practical nature; the formation of creative skills, the ability to apply knowledge in solving educational and practical problems. Each group includes several types of TR. The relationship between groups is explained by the fact that the same types of work can be used to solve various didactic problems.

KEYWORDS: *Process, Organization, Management, Independent, Student, Decision, Development, Creative, Activity, Continuity.*

INTRODUCTION

Improving the learning process at this stage addresses the problem of organizing and managing SQI (independent work of students)

puts it in one of the first places. For its effective solution, it is important to trace the development of the doctrine of independent creative activity and the continuity in the implementation of its main provisions. If we consider this problem a little more broadly, in relation to not only students, but students in general, then we can say with confidence that it has a rich history.

In Uzbekistan, the development of ideas about independent learning began in ancient times. In the writings of Ibn - Sina (the head of medicine in the world), Al-Khorezmiy (the master of the science of algebra), Al - Koshiy (the discoverer of the concept of fractional numbers) substantiates the importance of active independent human activity for the successful development of his thinking and improving his abilities. During the period of scholasticism and dogmatism of the Middle Ages, the philosophers F. Rabelais, M. Montaigne, T. Campanella urge teachers to bring up independence in their students so that they can choose the path of knowledge themselves. In more detail, the theoretical issues of independent activity of students were considered in the works of A. Disterweg, J.J. Russo, I.G. Pestalozzi [5].

In the first case, for the teacher, the student's development process remains hidden and, therefore, uncontrollable. Due to this, the formation of knowledge, skills and abilities during the implementation of the TR, if it affects the development of the student, his creative abilities, initiative and independence, then this influence is most likely spontaneous. At the same time, learning to a large extent loses its developmental and teaching functions. The second option is also erroneous and even harmful. The stereotyped performance of etudes without a meaningful selection of educational tasks and the desire to solve them inhibits the formation of a constant perception of nature, the development of a coloristic vision, and prevents the formation of professional abilities and skills. In this case, "quantity" very rarely turns into "quality". Even bigger problems arise in the transition to creative work.

The nature of the task in TRS and the degree of its complexity at different stages of training changes. The consistent complication of tasks is due to the need for such an organization of TR in the modern educational process, in which students not only master the system of knowledge, skills and abilities provided by the program, but also develop their creative abilities, form activity and independence. However, these goals are unattainable if students do not master the methods of performing a pictorial image.

Formulation of the problem: The didactic and methodological direction in the study of this problem was initiated by the works of the Czech teacher Ya.A. Komensky [6]. Until the middle of the 19th and 20th centuries, the independent activity of students was considered in the structure of pedagogical tools and teaching methods. For the first time, it was chosen as a direct subject of study in the works of the founder of national pedagogy A. Avlony, who analyzed the independent activity of students from a philosophical and psychological standpoint and tried to consistently describe the methods of forming independence and the original concept of teaching was developed by M. Dzhumaev. He considered the maximum freedom of students to be the basis of teaching, and considered independent work as the main means of developing their creative forces and abilities in teaching mathematics. The main research of domestic scientists in the field of the problem of this in students in the 60-90s. XX century are conducted in the following areas:

- essence, process and structure, classification of types and forms of SW (VN Bessonova, M. Khaidarov, etc.) [3];
- continuity in training and readiness for SW (YK Babansky, M. Dzhumaev, etc.) [2];

- classification of skills required for SW (E. N. Kabanova-Meller, J. Ikromova, etc.) [7];
- conditions for organizing and ways to improve the efficiency of SR (SI. Arkhangelsky, E.E. Zhumaev, etc.) [1].
- The conceptual provisions of cooperation pedagogy reflect the most important trends along which education is developing in a modern school:
- transformation of the School of Knowledge into the School of Education;
- placing the student's personality at the center of the entire educational system;
- humanistic orientation of education, the formation of universal values;
- development of the child's creative abilities, his individuality;
- identifying the development and support of gifted children;
- revival of national cultural traditions;
- education of a patriot of their homeland;
- upbringing of a physically and mentally healthy person within the framework of the valeologization of the education and upbringing system;
- a combination of individual and collective education;
- setting a difficult goal.
- Based on this goal, the concept of the development of the educational system consists of a certain set of sequentially implemented programs, each of which is responsible for a certain direction of educational work.
- The design of the education system is carried out through the use of the following educational and pedagogical technologies:
- technology of organizing and conducting group educational work
- - The goal is the formation of a relatively stable relationship of a person to himself, others, nature, things. Implemented through extracurricular activities (school-wide, classroom activities);
- health saving technology
- The goal is to preserve the physical and mental health of the child and teach the skills to preserve it. It was implemented through the holding of Days of Health, school-wide competitions, actions dedicated to promoting healthy lifestyles and preventing the use of psychoactive substances, alcoholism, tobacco smoking, suicidal behavior, the spread of HIV;
- physical culture and health technologies (FOT)
- The goal is the physical development of the trainees (hardening, training of strength, endurance, speed, flexibility and other qualities that distinguish a healthy, trained person from a physically weak person). It was realized in physical culture lessons and in the work of sports sections.
- ecological health-saving technologies (EHT)
- The goal is to create environmentally friendly, ecologically optimal conditions for the life and activities of people, harmonious relationships with nature. It was implemented through the arrangement of the school territory, landscaping of classrooms, recreation, participation in environmental activities, environmental competitions;

- technology for ensuring life safety (TFELS)
- Since the preservation of health is considered in this case as a special case of the main task - preservation of life - requirements and recommendations are subject to mandatory consideration and integration into the general system of health-preserving technologies. Students' literacy on these issues was ensured by studying the BLS course.
- project learning technology
- The goal is the independent and willing acquisition of knowledge from various sources, the development of the ability to use it, the acquisition of communication skills, the development of research skills and systems thinking. It was implemented through role-playing games, school-wide actions.
- Inrmation and communication technology (ICT)
- The goal is the formation of skills to work with information, the development of communication skills of students, the preparation of the personality of an "informed society", the formation of research skills, the ability to make optimal decisions.
- ICTs are called interactive, as they have the ability to "respond" to the actions of the student and teacher, "enter" into a dialogue with them. It is implemented in the lessons of informatics and ICT, in extracurricular activities, in the independent project activities of students.
- teaching technology
- The goal is to take into account the individual characteristics of students in such a form when they are grouped on the basis of any characteristics for a separate teaching. It is implemented in the work of circles, sports sections, extracurricular activities.
- technology of social design (social education of students)
- The goal is to create conditions for social tests of personality.
- technology of personality-oriented education and training
- The goal is the development and self-development of the student, his formation as a person, taking individual characteristics, interests and abilities into account. A personality-oriented approach is a methodological position in pedagogical activity that allows, through relying on a system of interrelated concepts, ideas and methods of action, to provide and support the processes of self-knowledge, self-construction and self-realization of the child's personality, the development of his unique individuality [10].

Results

Independent work of students is divided into classroom and extracurricular. It is one of the forms of the educational process, its essential component.

The study of scientists - teachers and psychologists allows us to conditionally distinguish four levels of independent productive activity of students, corresponding to their educational capabilities:

1. Copying actions according to a given pattern. Identification of objects and phenomena, their recognition by comparison with a known image. At this level, preparation for independent activity takes place.
2. Reproductive activity for the reproduction of information about the various properties of the object under study, basically not going beyond the memory level, but involving the solution of more complex but typical problems.

3. Productive activity of independent application of the acquired knowledge to solve problems that go beyond the known pattern.

4. Independent activity on the transfer of knowledge when solving problems in completely new situations.

I believe that any independent work, at any level of independence, has a specific goal. Independent work should correspond to the student's educational capabilities, the degree of complexity, satisfy the principle of a gradual transition from one level of independence to another. The main goal of independent work is not only to consolidate, expand and deepen the acquired knowledge, skills and abilities, but also to independently study and assimilate new material without outside help. Many students experience great difficulties associated with the lack of analysis skills, note taking, working with primary sources, the ability to learly express their thoughts, plan their time and take into account the individual characteristics of their mental activity.

The teachers of the department create educational and methodological complexes (EMC) for individual disciplines - pedagogical assistance to students in independent educational and cognitive activities. Since independent work is the most important form of the educational process, teachers focus the attention of students on its direct influence on the formation of such parameters of the qualification characteristics as mobility, the ability to predict the situation and actively influence it so that students see the positive results of their work and so that success in learning contributes to transformation mediated learning in immediate interest. The formation of such motivation is facilitated by the sincere interest of teachers in the success of students.

The leadership of the independent work of students by the teacher should gradually move into self-government and self-organization of the student as a subject of learning.

One of the forms of students' independent work is course design. In order to work effectively and completely independently, students need to show activity, intellectual initiative, meaningly, they have to try to find unique non-standard approaches to the activity.

A promising stage in the implementation of independent work is a production workshop. At the same time, the teacher acts as a consultant and monitors the student's activities.

To stimulate and constantly maintain students' interest in obtaining new knowledge, more attention should be paid to teaching their self-education system. Students must master the basic and individual specific constituent elements of the teacher's work: work with scientific, methodological and educational literature; present educational material, compose a system of differentiated exercises and manage it in the process of solving a problem; use the techniques of posing a question, formulate organizing and governing questions, as well as versions of the same question; quickly and adequately respond to the emerging educational situation; be able to control and evaluate knowledge, etc. Independent work of students is their activity in the learning process and in extracurricular time, carried out on the instructions of the teacher, under his guidance, but without his direct participation.

The main features of students' independent work, with perceived information, are considered to be:

- The presence of a cognitive or practical task, problematic issue or task and special time for

their implementation, solution;

- Manifestation of mental tension of the students' thoughts for the correct and best performance of this or that action;
- Manifestation of consciousness, independence and activity of students; In the process of solving the assigned tasks;
- Possession of skills of independent work;
- Implementation of management and self-government of independentcognitive and practical activities of the student.

The core of independent work, the starting point of its construction, is a cognitive or problematic task. It is the presence of a task that determines the entire process of independent work: it provides for the independent activity of students to solve the assigned tasks; compulsory preparation for self-fulfillment, solving educational and professional tasks. In various forms of the educational process, the independence of students manifests itself in different ways: from simple reproduction, performing a task according to a strict algorithmic scheme using cursive writing techniques, speed reading, etc. to self-creativeness. The independence of students in the study of special subjects is manifested through their planning of their academic work; selection of educational literature, teaching aids for self-study; preparation of demonstration equipment and its application; fulfillment of individual educational tasks and holistic work in the specialty on samples of literature and technology without direct help and detailed instructions from the teacher [11]. The functional purpose of independent work of students in the process of lectures, seminars, practical exercises on mastering special knowledge is to independently read, view, listen, observe, take notes, comprehend, memorize and reproduce certain information. The teacher determines the goal setting and planning of independent work for the student. All information is carried out on the basis of its reproduction.

Independent work of students is also manifested in the extracurricular time, when students repeat the educational material and deepen their theoretical knowledge with the help of special literature or computer teaching devices.

Properly organized independent work of students is of great educational value. It is a defining condition for achieving high results in education, in the formation of moral qualities; serves as a primary method of converting acquired knowledge into beliefs and skills, is an important factor in the development of learning abilities, engages in self-education and is therefore a means of education and purpose.

It should be noted that for a long time the problem of SR was solved only in relation to the process of teaching at school. With regard to the educational process of the university, it began to be addressed much later.

Since the 1970s, various aspects of organizing and conducting CDS have been actively discussed at conferences of various faculties of universities in the country and are presented in collections of scientific papers.

In many studies, CDS is considered in terms of its intensification, which involves not only strengthening the teacher's activities to increase the activity of students, but also solving the whole range of issues related to improving the quality and efficiency of extracurricular work.

Expansion of controlled educational independence of students, based on SR in their free time from official classes, is the main trend in the development of the didactic process in higher education in the largest foreign countries [4].

In the USA, Germany, England, France, Austria, Japan, there are entire government structures that develop global plans and programs for student self-development. In these countries, special attention is paid to providing students with targeted assistance in self-development, knowledge of their individual characteristics, overcoming difficulties arising in the learning process and in choosing the optimal training plan.

For Western schools in the 20s - 30s. XX century characteristic didactic concepts of "reformatory pedagogy" (V. Lay, A. Binet, D. Dewey, etc.). Teachers of this period believed that it would be more correct to create a "school of action" instead of a "school of learning." The student himself must be an active participant in his own learning. Representatives of new ideas (J. Demeny. D. Dewey. G. Kershenshteiner) urge to proceed from the interests of the students themselves and to encourage their independence in every possible way. at present, these ideas of reformatory pedagogy are applied in practice in the modern schools of the West.

Scientists call the individualization of teaching and the development of creative activity and independence of students one of the leading principles of pedagogy. The latter is considered by teachers from different countries in different ways. .Dewey in his work "School and Society" notes that all learning should be conducted by self-solving students' problems and awaken their curiosity.

Existentialist educators from the USA, France, Great Britain and Germany view the principle of independence from a slightly different angle. In their opinion, it is necessary to individualize learning, understanding this as giving everyone the opportunity to go their own way and receive education to the best of their "allowed abilities." In recent years, this concept has theoretically justified many new projects in the field of learning.

To ensure the adequacy of the understanding of our research, it is advisable to consider the evolution of the concepts of TR, as well as to determine the initial positions and content of the terms that we will operate in the future. In modern philosophical, psychological, didactic and methodological literature, various aspects of TR of pupils and students are considered. However, there are certain difficulties in solving some issues. So, for example, there is no uniform interpretation of the concept of "creative work".

In our opinion, this definition also refers to traditional teaching, since it assumes a decisive role in the organization of this activity of the teacher. In the system of developing education, TR should presume the possibility of guiding a book, communicating with fellow students, and, if possible, with specialists, in our case – painters. Educational and creative work performed by a student is not deprived of the status of independence because the author consults with his supervisor, talks with friends, meaningly, takes part in expedient communication, which is creative not only in the creative process, but also in the educational process.

Considering all this, in this study, TR is understood as an educational process aimed at developing students' abilities to consciously set goals and objectives for themselves, plan their educational and creative activities, implement them and evaluate them objectively.

In our understanding, the concept of "creative work" has a double meaning. On the one hand, TR is a work that a student performs independently, it is an object of his activity. It is offered to the student by a teacher or a creative work program. On the other hand, TR is a form of manifestation of the corresponding activity of thinking, memory, and creative imagination, fantasy when a student performs an educational and creative task, which, ultimately, leads him to obtain new knowledge previously unknown to him or to deepen and expand areas of application of already acquired knowledge. In both cases, TR contributes to the development of the intellectual and creative powers of the student.

Since there is independence in any educational process: students themselves listen to the teacher's explanations, observe nature themselves, write sketches themselves, this is also TR, we will specially note that in the future we will talk about extracurricular or home TRS. Currently, the most widespread idea is that creative activity includes motivational, cognitive, emotional-volitional and reflexive components.

The motivating factors are the personal qualities of students: curiosity and creative interest, emotionality, enthusiasm, desire for creative achievements, desire for leadership, a sense of duty and responsibility, personal significance of creative activity, desire for self-education and development of creative abilities. The degree of development of these qualities characterizes the motivational and creative activity and self-activity of students.

In addition, for effective TR, it is necessary to develop students' abilities for self-government: purposefulness, the ability to plan and use time efficiently, diligence, self-control and self-assessment of abilities and achievements. Although the named motives do not exhaust their diversity, they more than others stimulate the cognitive and creative activity and independence of students, awaken their desire to work, improve their knowledge and skills.

Self-organization and self-control, that is, conscious work on oneself in order to improve one's skills, play a special role. The most important components of self-organization are a responsible attitude to business, high interest in the chosen specialty, developed self-consciousness and creative thinking.

Conclusion

The basis of TR is the connection "goal - means - control". Its success is determined by the student's ability to regulate his actions with a conscious goal. These actions, aimed at acquiring knowledge, skills and abilities, cause a certain process in the student's behavior, motivated by one or another need, serving both as an incentive and as a goal.

Thus, TRS on the subject, like any other activity, has the following structure: motive, performance and control. In a generalized form, in the structure of the TRS, one can distinguish:

1) The content side (knowledge expressed in terms or images of perceptions and ideas);

2) The operational side (various actions, operating with skills, methods and techniques);

3) The productive side (new knowledge, skills, solutions; new visual experience, ideas,

attitudes, abilities and personality traits).

All of them are interrelated and should be taken into account in the process of organizing and implementing TRS.

When performing TR, the student correlates his actions and their sequence with the requirements of the task and consciously controls his activities. The process of performing TRScarried out in the following order:

1) The allocation of goals and objectives (anticipation of the final result and determination of the general conditions for its achievement);
2) Solution of the problem (selection and application in the required sequence of adequate methods of action leading to the solution of the problem, determination of the necessary means for their implementation);
3) Self-control (comprehension of the work done: is the task set by the found and applied methods being solved, or is it necessary to correct them).

The external form of TR is a task. The internal content is an educational or creative task offered to the student at a specific stage of learning. "The essence of independent work is determined by the peculiarities of cognitive tasks embodied in the specific content of types and types of creative work" [1, p. 151].

The student mobilizes the previously acquired knowledge of the accumulated experience of activity in accordance with the task of the new exercise.

The absence of a clearly formulated task in the TR, which is often found in modern teaching practice, leads to the fact that the process of its implementation remains, at best, neutral in relation to the nature of students' creative activity. So, how many works a student independently performs, the process of his intellectual and creative development in the course of performing this work proceeds either according to the principle of "trial and error", or according to a pre-established template, familiar scheme: a certain number of similar works are performed for viewing (according to students, "for quantity"). Both of these paths are extremely ineffective.

The assimilation of educational material, as evidenced by numerous psychological studies and the data of our experimental work, occurs most effectively when it is included in the structure of creative educational activity of students in the form of interrelated educational tasks.

A more versatile approach to solving the problem of TR classification was used in the work of A.V. Usova [2]. Unlike previous authors, it does not exclude the possibility of classifying TR types according to various attributes. It is only necessary that the selected feature is the most important in solving a particular pedagogical problem. For example, the author proposes to classify TR according to the main didactic goal.

Putting this feature as the basis for the classification, we subdivide it into five groups: the acquisition of new knowledge and the mastery of the skills to independently acquire knowledge; consolidation and refinement of knowledge; developing the ability to apply knowledge in solving educational and practical problems; the formation of skills and abilities of a practical nature; the formation of creative skills, the ability to apply knowledge in solving educational and

practical problems. Each group includes several types of TR. The relationship between groups is explained by the fact that the same types of work can be used to solve various didactic problems.

The above review of various directions and approaches in solving the problems of determining and classifying TR proves that these problems have attracted and continue to attract the attention of methodologists and didactics.

IWS is an obligatory component of educational activities, therefore, it needs a thorough methodological study and recommendations for its organization at faculties and departments. Analysis of the methodological literature showed that the problems of independent activity are developed in theoretical terms rather deeply. However, the specifics of universities are different, so it is impossible to find the same solutions for everyone.

Earlier, I described some of the methods of students' perception of information. And I agree with those methods that require that, in addition to lectures and textbooks, the student also pays attention to special literature, electronic library, etc. I believe that the student most fully and deeply perceives only the information that he himself used and improved in the process of his activity, and no one will force him to perceive and process it if he does not want to.

One of the most important principles of modern university education is the ability to independently “learn to learn”.

To develop a program of independent work of students and systematically monitor its implementation for each course, again in the context of teaching drawing, but , in our opinion, this is just as important when organizing the educational process in other special disciplines of mathematical education.

With regard to the study of the foundations of mathematics at the Faculty of Physics and Mathematics, the SRS system has not yet been the subject of special research and requires a comprehensive study.

APPLICATION OF INTERNET OF THINGS IN AGRICULTURE

Mr. Manoj Kumar Ojha*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: manoj@sanskriti.edu.in

ABSTRACT

The Internet of Things (IoT) is a concept that enables physical devices with computational and sensory support to communicate with one another and access Internet-based services. The Internet of Things (IoT) concept was developed to link gadgets through the Internet and make information more accessible to consumers. IoT has a broad variety of possible applications, including agriculture, where IoT will be used extensively in the future. The purpose of this paper was to introduce the Internet of Things (IoT) idea as a foundation for monitoring and control systems utilized in agricultural production operations. IoT devices are important, with an emphasis on implementing them using existing microcontroller platforms and suitable sensors, such as Arduino products. In monitoring systems, autonomous sensor devices collect data and participate in the control process by providing signals to actuators. Users may remotely monitor conditions and manufacturing processes using an IoT-based solution like this. This technology allows customers to save money on inputs, reduce costs, and track the production process on the farm.

KEYWORDS: *Agriculture, Arduino, Drones,Internet of Things, Monitoring.*

1. INTRODUCTION

Every item that can be controlled via the internet is an Internet of Things (IoT) device. Wearable IoWT (Internet of Wearable Things) gadgets like smartwatches and home management solutions like Google Home have made IoT devices very popular in consumer markets. By 2020, it is expected that over 30 billion gadgets will be linked to the Internet of Things. IoT applications in farming are aimed at traditional agricultural activities in order to satisfy rising demand and reduce output losses. Robots, drones, remote sensors, and computer imagery, in combination with ever improving machine learning and analytical tools, are used in agriculture to monitor crops, survey and map fields, and give data to farmers for sensible farm management plans that save time and money[1]. Agriculture uses IoT to get insights and monitor farms via the use of robotics, drones, sensors, and computer imagery combined with analytical tools. Physical equipment placed on farms monitors and collects data, which is then utilized to get insights.The Internet of Things (IoT) is the concept of using the Internet to link physical items with sensing, networking, and computing capabilities to other objects and services. Although the fundamental

idea behind IoT isn't new, IoT makes advantage of a wide range of devices and their network connectivity via the Internet. As a result, the IoT idea guarantees that any device is accessible through the Internet, resulting in significant changes in terms of network interconnections .Agricultural crop production and domestic animal breeding have both been impacted by technology advancements in the past decade[2]. Farmers may get information on soil humidity, nutrient condition in the soil, and the presence of plant diseases and pests in plants using different sensors and wireless devices. Farmers can respond quickly and take appropriate action based on the information they have received. Sensors collect data on the operation of agricultural equipment, allowing operators to adapt machine operation to working circumstances in order to improve the efficiency and quality of the production process[3]. IoT gives conventional agriculture a new perspective on production, focusing on the information network, which includes automation, the use of intelligent devices, and their networking in the agricultural production process. Improvements in the efficiency of inputs such as soil, water, fertilizers, pesticides, and other inputs, as well as lower production costs, improved profitability, sustainability, food safety, and environmental protection are all advantages of IoT applications in agriculture[4]. Farmers can distribute their products to consumers on a large scale because to the Internet of Things. This has the potential to alter the supply chain, making it more directed and shorter from the place of production to the customer. The goal of this paper was to introduce the Internet of Things (IoT) idea in a monitoring and control system model for agricultural production operations. Furthermore, the emphasis is on IoT device definitions and implementations using available microcontroller platforms, shields, and suitable sensors, such as Arduino products[2]. IoT nodes are built on Arduino platforms with readily accessible shields and suitable sensors, as well as strong library support[4].

Demonstrated a gateway platform that allows physical things to connect to the Internet.The suggested architecture was implemented on Arduino platforms and specifies the development of Internet of Things services that allow local sensors to be accessible through LAN or the Internet. Arduino-based sensor devices link to LAN networks, allowing them to be accessed. This is accomplished by embedding Ethernet or Wi-Fi modules into sensor devices, enabling them to communicate with one another. For Ethernet connections, the Arduino ENC28J60 Ethernet Module is utilized, while the ESP8266 Module is used for wireless connectivity.

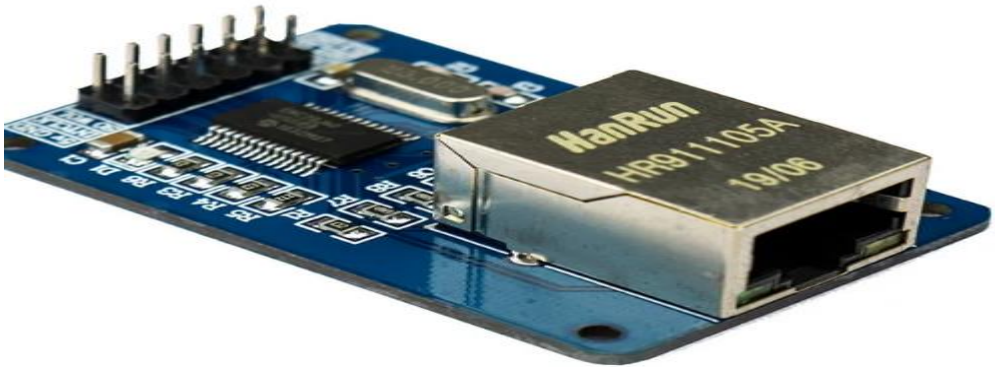

Figure 1: Diagrammatic Representation of Arduino ENC28J60 Ethernet Module [ELECTRONIC HUB]

To meet network protocol requirements, the Ethernet module utilizes a new Microchip ENC28J60. The SPI interface connects the module to most microcontrollers. It features a +3.3 V power supply and a transmission rate of up to 20MHz (ENC28J60 Ethernet).depicts the Arduino Ethernet. It includes an Arduino development board based on the ATmega328 microcontroller, as well as an Ethernet interface on the same board. An external power source, an optional PoE module, or an FTDI cable/USB Serial connection are used to power this board (Arduino

Ethernet). The ESP8266 is a WiFi networking solution that allows you to connect your microcontroller to the internet [5]. It also has the ability to execute several programs at the same time. The following are the specifications for the ESP8266 Module: 3.3V power supply, 32K + 80K RAM, 80-160MHz CPU, and 802.11 b/g/n/d/e/i/k/r support The transmitting current consumption may be as high as 170mA at full power, yet just 10uA in sleep state This module's battery power source may include a solar panel for battery recharge.

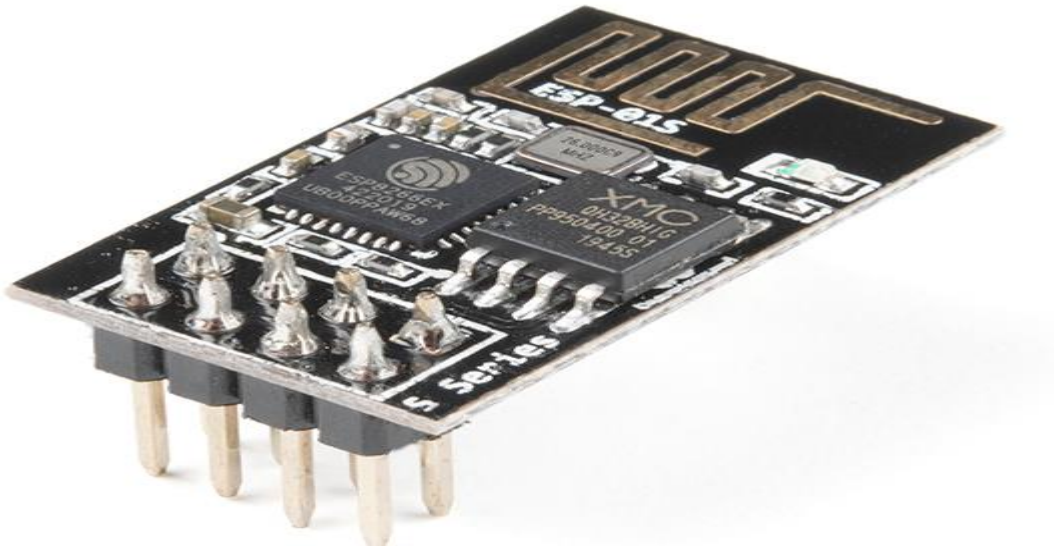

Figure 2: Diagrammatic Representation of ESP8266 Wi-Fi Module [ELECTRONIC HUB]

1.1 **Application Of IoTinAgriculture:**

- **Precision Farming:**

When it comes to producing animals and cultivating crops, precision farming may be defined as anything that makes agricultural practices more regulated and precise. The utilization of IT and other things such as sensors, control systems, robots, autonomous vehicles, automated hardware, variable rate technologies, and so on is a major component in this approach to farm management. Precision agriculture is characterized by the use of high-speed internet, mobile devices, and dependable, low-cost satellites (for imaging and location) by the manufacturer, to name a few important technologies.Precision agriculture is one of the most well-known IoT applications in the agricultural industry, and many companies use it all around the globe. CropMetrics is a precision agriculture company that focuses on cutting-edge agronomic solutions and specializes in precision irrigation management. CropMetrics' products and services include VRI optimization, soil moisture probes, and the virtual optimizer PRO, among others. VRI (Variable Rate Irrigation) optimization improves yields and enhances water usage efficiency on irrigated agricultural areas with topographical or soil variability. The soil moisture probe technology offers full in-season local agronomy assistance as well as suggestions for water usage efficiency optimization. The virtual optimizer PRO integrates different water management technologies into a single, cloud-based, and powerful location enabling consultants and farmers to take advantage of precision irrigation advantages via a simple interface.

- **Agricultural Drones:**

Agricultural drones are an excellent illustration of how technology has evolved through time. Agriculture is becoming one of the most common sectors to use drones. Drones are being utilized in agriculture to improve a variety of farming techniques. Crop health evaluation, irrigation, crop monitoring, crop spraying, planting, and soil and field analysis are some of the

ways drones are utilized in agriculture, both on the ground and in the air. Crop health imaging, integrated GIS mapping, simplicity of usage, time savings, and the potential to improve yields are all advantages of utilizing drones. Drone technology will offer the agricultural sector a high-tech makeover with strategy and planning based on real-time data gathering and processing. PrecisionHawk is a company that utilizes drones to collect useful data through a set of sensors that are used for agricultural land imaging, mapping, and surveying. In-flight monitoring and observations are carried out by these drones[6]. Farmers select the land they want to survey and choose an altitude or ground resolution. Plant health indices, plant counting and yield prediction, plant height measurement, canopy cover mapping, field water ponding mapping, scouting reports, stockpile measuring, chlorophyll measurement, nitrogen content in wheat, drainage mapping, weed pressure mapping, and so on can all be derived from drone data. During the flight, the drone gathers multispectral, thermal, and visual images before landing in the same area from where it took off.[7]

- **Livestock Monitoring:**

Wireless IoT apps may be used by large farm owners to gather data on their cattle's whereabouts, well-being, and health. This information assists them in identifying ill animals so that they may be removed from the herd, avoiding disease transmission. Ranchers may use IoT-based sensors to find their livestock, which reduces labor expenses. JMB North America is a company that provides cattle farmers with cow monitoring systems[8]. One of the options aids cattle owners in observing pregnant cows on the verge of giving birth. When the heifer's water breaks, a sensor powered by a battery is ejected. This communicates with the herd manager or rancher. The sensor allows farmers to be more focused when working with heifers who are giving birth.

- **Smart Greenhouse:**

Greenhouse farming is a technique for increasing the production of vegetables, fruits, and other crops. Manual intervention or a proportional control system are used in greenhouses to regulate environmental factors[9]. These techniques are less successful since human intervention leads in production losses, energy losses, and labor expenses. With the assistance of IoT, a smart greenhouse may be created; this design automatically monitors and regulates the temperature, removing the need for human intervention. Different sensors that monitor environmental factors according to the plant need are utilized to regulate the environment in a smart greenhouse. When the system is linked through IoT, we may set up a cloud server to provide remote access. This removes the need for ongoing manual supervision. The cloud server also processes data and performs a control action within the greenhouse. With little human involvement, its design offers farmers with cost-effective and optimum solutions. Aluminum Greenhouses is a drip irrigation and Agri-Tech greenhouse company that provides services using cutting-edge technology. It utilizes solar-powered IoT sensors to create contemporary and inexpensive greenhouses. The condition of the greenhouse and water usage may be tracked with these sensors through SMS notifications to the farmer via an internet site. In these greenhouses, automatic irrigation is used.Lightlevels; pressure, humidity, and temperature are all measured by IoT sensors in the greenhouse. These sensors may automatically operate the actuators to open a window, switch on lights, regulate a heater, turn on a mister, or turn on a fan, all through a Wi-Fi connection.

2. LITERATURE REVIEW

P. Prabavathi[2]proposed that Modernization of the farming process is one of the most important steps for a country like India, which has to import a large amount of grains other agricultural products from other countries to meet the demands of its 1.2 billion people. One of the most challenging aspects of agribusiness is determining the soil's health, nature, and changing the water system and plant clear according to this view. Horticulture issues are wide open, and agriculturists have been blocking progress for a long time. Rural modernisation is the primary

solution to these problems. Another example is providing protection in fields or grain storage against rat or creepy crawly attacks. Farming modernization is realized via a 'Web of Things'-based device that is capable of detecting data and sending it to the client. This device can be operated and monitored from afar to ensure the security of grain storage and agricultural areas.

K. E. Nalina and R. Kaliwal[10]proposed that IoT (Internet of Things) is a current and future developing technology. It functions as a common network that connects items and things via the internet. The Internet of Things (IoT) aids farmers in resolving significant issues. Due to India's overpopulation and lack of rainfall, agriculture is the primary source of income for farmers. We are having difficulty sustaining our everyday supplies such as water, food, and crops, among other things. To address these issues, we devised this project, which combines IoT with a low-cost system for monitoring soil characteristics in agricultural fields, such as soil condition, temperature, and humidity. This system includes an ESP8266 Wi-Fi module, an Arduino UNO microcontroller, GSM, and Arduino-based sensors. The system is GSM-enabled, allowing data to be sent to a user's mobile phone through SMS.

S. Gavaskar and A. Sumithra[9]proposed that Because the issue of agriculture is now solved manually, there are more opportunities for farmers to lose money. Agriculture is now shrinking as a result of increased pollution and pests across the globe. The majority of farmers in India cultivate sugarcane; however it does not yield owing to bugs and larvae in the sugarcane. To prevent this, the suggested design includes an acoustic sensor as well as a pir sensor. The noise and temperature were monitored using an Arduino in this suggested design system. As a result, locating the issue may be simplified and addressed quickly.

3. DISCUSSION

In agriculture, IoTs have been used to increase agricultural yields, enhance quality, and lower expenses. For these reasons, we suggest in this article that WSNs be used to irrigate crops. We devised and developed a method for regulating environmental variables in agricultural fields.The hardware, online application, and mobile application were all part of the system. The initial component was planned as a control box and executed. This control box included both hardware and an electronic control system for connecting to sensors and obtaining agricultural data. The control box was created with real-world testing in mind. In this research, the implemented design linked to and received IoT data from any field. The web-based application, which was developed and built to modify crop data and field information, was the second component. Large-scale data from the Internet of Things is stored and analyzed in this phase. This study made a significant contribution by using data mining with association rules to find valuable information on the impacts of the environment and climate. The temperature range for excellent production of homegrown veggies and lemons was found to be between 29 and 32 degrees Celsius. Furthermore, the ideal humidity for maximum lemon production was between 72 and 81 percent.The last step was to use a smartphone application to manage the crop irrigation. This provided the user with both automated and manual functional control. For watering, the user may utilize the automated feature, which is based on data from soil moisture sensors. In the functional control mode, however, manual control was feasible. The system used the LINE application's LINE API to send alerts.

4. CONCLUSION

This article examines the literature on IoT in agriculture and offers an overview of current applications, enabling technology, and the major obstacles that lie ahead. The study reveals that the topic drew a lot of interest from the scientific community, particularly in China. Food supply networks and arable farming are the most often discussed topics. The significance of food safety and food quality management explains the prevalence of papers dealing with food supply networks. The focus on arable farming may be explained by the fact that IoT is often seen as a

next step in the evolution of the precision agriculture idea. Furthermore, exploratory articles and research that showcase IoT systems that are developed or deployed in prototypes or pilots predominate in the examined literature. The articles examined are mostly concerned with sensing and monitoring, with actuation and remote control receiving little attention.When it comes to connection, the focus is on various kinds of wireless sensor networks. The majority of IoT applications concentrate on fundamental functions such as tracking, tracing, monitoring, and event management. These results show that, although the Internet of Things is gaining traction, it is still in its infancy in the agricultural and food industries. Applications are often fragmented, lack smooth integration, and are still in the experimental stage of development, particularly for more sophisticated solutions. Integration of existing IoT solutions with open IoT architectures, platforms, and standards, (ii) upscaling the use of interoperable IoT technologies beyond early adopters, particularly through the simplification of existing solutions and making them more affordable for end users, and (iii) further improvement of IoT technologies to ensure a b The majority of generic technological components to solve these problems should be accessible soon. Agriculture and food will be transformed into smart webs of linked items that are context-sensitive and can be recognized, sensed, and controlled remotely as a result of the Internet of Things. This is anticipated to have a significant impact on agri-food processes, resulting in new regulatory mechanisms and economic models. As a result, we think that the Internet of Things (IoT) will be a game changer in agriculture and the entire food chain, significantly increasing production and sustainability. For example, IoT will assist farmers in transitioning to data-driven farming, which will be aided by decision-making tools that use real-time and accurate operational data. As a consequence, farms may shift from a supply-oriented, cost-driven, anonymous strategy to a value-based, information-rich one in which demand and supply are constantly matched. Farms and food supply chains may eventually become self-adaptive systems in which smart, autonomous things, such as agricultural equipment, can function, decide, and even learn without human involvement on-site or remotely.

ABSTRACT

The application of nanotechnology in electronics is known as nanoelectronics, where nano refers to a very tiny range that cannot be seen with the human eye. Nano represents a diverse collection of devices, materials, instruments, and equipment, all of which have at least one comparable or common characteristic: their size is so tiny that their interatomic interaction and quantum mechanical characteristics must be investigated. Nanotechnology is a broad phrase that encompasses a wide range of disciplines such as science, research, and technology. Nanotechnology is also utilized in the food sector, as well as in information and communications technologies and electronics. Nanotechnology is concerned with the handling of tiny objects and processes. This study discusses one of the nanoparticles known as cantilever, as well as its use, limitations, and future need. This effect is also shown in this article, where the output of a cantilever changes as its energy level changes. Nanotechnology is an area of research that entails the study, design, manipulation, production, and control of materials, devices, and equipment using physical or chemical methods. Nanotechnology has been used to a variety of applications, including industry and medicine. Many therapeutic devices, including nanotechnology, are utilized to cure cancer; nanotechnology targets cancer bacteria or cells exclusively, causing no damage to healthy tissue; nanotechnology may also be employed in pharmaceutical goods, namely sunscreen. This research paper looked at the science underlying nanotechnology and how it may be used to various fields such as industry and medicine.

KEYWORDS: *Small, Micro, Molecular Study, Nano Electronics, Quantum Dots, Nanoscale, Quantum Size Effect, Fullerene, Quantum Computers.*

INTRODUCTION

Nanotechnology is essentially the study of molecules, as shown by the fact that it involves the manipulation, design, and creation of matter. Different types of force are applied to atoms and molecules so that their properties can change according to the needs of industry. Because the size of particles is very small in nanometers and the study of this is very complicated, scientists and engineers are occupied with resolving the atoms and their bonds' complexity[1].

The application of nanotechnology in electronics is known as nanoelectronics, where nano refers to a very tiny range that is not visible to the human eye[2]. Nano represents a diverse collection of devices, materials, instruments, and equipment, all of which have at least one comparable or common behavior: they are very tiny in size, so small that their interatomic interactions and quantum mechanical characteristics must be studied. Nanotechnology is a broad phrase that encompasses various areas such as science, research, and technology [4]. In addition to the food sector, nanotechnology is utilized in information technology and electronics. Nanotechnology is concerned with working with tiny objects and performing small processes[3].Fig 1 shows the structure and design of nanoparticle it's basically for the molecules and atoms.

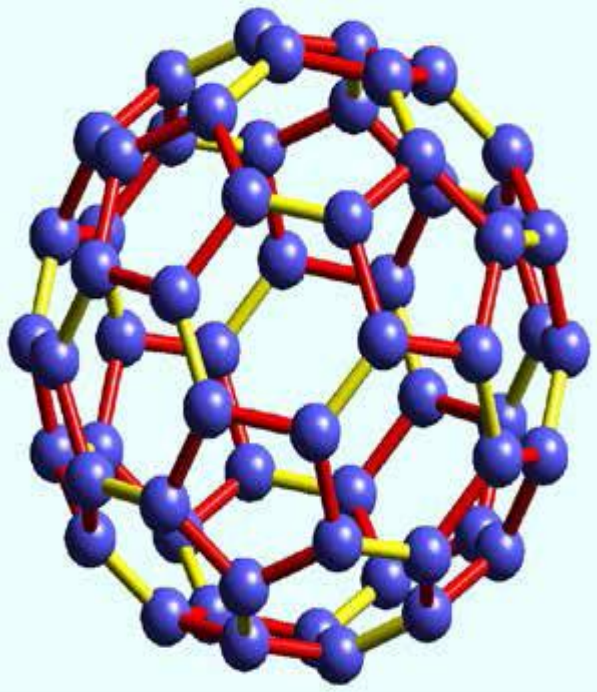

Fig 1: The Structure and Design of Nanoparticle It's Basically for the Molecules and Atoms.

Nanotechnology is the study based on nanoparticles; Fig 1 shows the structure and design **of** nanoparticle it's basically for the molecules and atoms of any matter, there are many different types of nanoparticle presents and all nanoparticle have different industrial application as shown in the figure 2, among all the nanoparticle one nanoparticle named cantilever has been discussed in this paper also its application and output of the application shown in this paper[4].

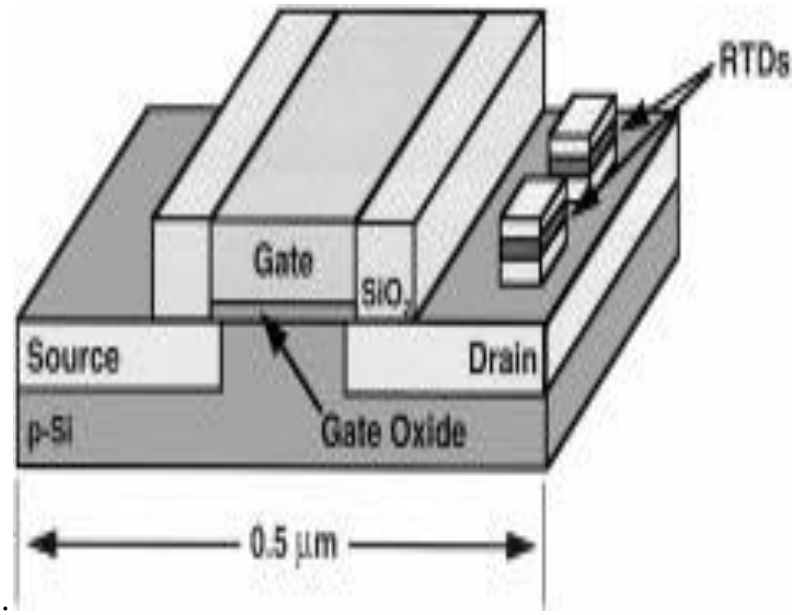

Fig 2.1:All Nanoparticle have Different Industrial Application.l

Nanotechnology has different application and potential field of work like it is also used in textile such as Nanotechnology can be defined as the tool of measurement, prediction and construction of materials of different properties by playing or changing their atomic or molecular behavior, the scale of their change is in nanometers[5]. Atoms and groups of atoms called molecules are very small in nature also their small size creates complexity in work so scientists and engineers are trying to take control of these small particles also they take control over atoms and molecules individually, manipulating them to use with an extraordinary degree of precision[6].The mutation stage 1 and 2 is shown in the Figure 3 and Figure 4.

Atomic Power AFM used to put force on the atom of matter so that its characteristics and work change. Microscope is a device that operates on the concept of nanotechnology in which a force is placed on the atomic portion of the sample matter. shows a list of nanotechnology-based modality and potential applications, and table 1 shows which nanoparticles have been used for which technology or purpose, such as quantum dots, which is a nanoparticle used for optical detection of gene and protein in animals and cells assays, and in tumor and lymph node visualization, and nanowire, which is a nanostructure used for tumor and lymph node visualization. Nanoshells are a type of nanoparticle that is used for tumor specific imaging. Nanoparticles are defined as small particles of matter that have a wide range of applications in industry, including targeted drug delivery permeation enhancers, MRI and ultrasound image contrast agents, and reports of apoptosis and angiogenesis, among others. Dendrimers are repetitively branched molecules that are used in the application of targeted drug delivery permeation enhancers, MRI and ultrasound image contrast agents [7].

LITERATURE REVIEW

Many research papers have been published in the field of nanotechnology and its application in medical and industrial processes. In a research paper titled an introduction to nanotechnology

and its implications by Shree KantaSubedi Department of physics, Prithivi Narayan campus, Pokhara, the author discusses the study of nanotechnology and its historical background, as well as the use and implications of nanotechnology. This paper has shown nano particles such as carbon nanotubes and buckyballs. Nanotechnology can be used in many sectors, one of which is the energy sector. Nanotechnology also has a very broad career and opportunity, so it is used in the development of quantum computers. Nanotechnology can also measure reactivity and strength of materials [8].

In a research paper titled Overview of Nanoelectronic Devices, David Goldhaber-Gordon, Michael S. Montemerlo, J. Christopher Love, Gregory J. Opiteck, And James C. Ellenbogendiscussed the molecular structure that has been studied in nanotechnology, as well as the different sizes of the particle that fall into which range of nanotechnology. Which are based on the nanotechnology concept, Discussed are the structure and operation of a MOSFET, Obstacles to Further Miniaturization of FETs, solid state quantum effect and single electron nanoelectronic device, and the study of RTD (resonant tunneling diode), graph and structure, nanoelectronic device taxonomy, and molecular electronic switching devices. This research article also covers electronics molecules, providing a short overview of the types of technologies utilized to investigate molecules, as well as the many methods and perspectives on materials that nanotechnology may provide [9].

NSI addressed the idea for future high-performance hybrid nanophotonic devices in a research article titled Highlights from the Nanoelectronics for 2020 and Beyond (Nanoelectronics) with a nice graphic of the same, Reversible molecular switch created by Bissel et al. As explained in the text, ring-like "bead" molecules move along wire-like chain molecules to accomplish switching operations. In this study article Reversible molecular switch created by Bissel et al., nanotechnology was also utilized to run large operations by altering tiny molecules' behavior on a very small scale. As explained in the text, a ring-like "bead" molecule moves along a wire-like chain molecule to provide a switching function [10].

DISCUSSION

The application of nanotechnology in electronics is known as nanoelectronics. Nano refers to a very tiny range that is not visible to the human eye. Nano represents a diverse collection of devices, materials, instruments, and equipment, all of which have at least one comparable or common characteristic: their size is so tiny that their interatomic interaction and quantum mechanical characteristics must be studied. Nanotechnology has a wide range of applications in engineering, medicine, and industry because atomic control is a very excellent and effective instrument for the future. Nanotechnology has the ability to ignite and transform us from head to toe by implementing and bringing about a variety of complicated alterations. Many complicated and difficult interactions occur at a very tiny scale thanks to nanotechnology. The application drawbacks and output waveform of the cantilever waveform are shown in this paper. Cantilevers are used for a variety of applications, including high throughput screening, disease protein biomarker detection, DNA mutation detection [SNPs], and gene expression detection. They are also used to apply force to atoms and molecules, as well as to create contact between molecules. While increasing or reducing energy and total system enthalpy, the output waveform of current is illustrated with various values of current waveform.

Because it includes the manipulation, design, and production of matter, nanotechnology is basically the study of molecules. Atoms and molecules are subjected to various kinds of force in order for their characteristics to alter in response to industrial demands. Scientists and engineers are preoccupied with resolving the intricacy of atoms and their connections since particle sizes are extremely tiny in nanometers and studying them is quite difficult. Nano electronics is the use of nanotechnology in electronics, where nano refers to a very small range that is not visible to

the naked eye. Nano is a broad term that refers to a wide range of devices, materials, instruments, and equipment that all have at least one similar or common characteristic: they are very small, so small that their interatomic interactions and quantum mechanical properties must be investigated. Nanotechnology is a wide term that refers to a variety of fields, including science, research, and technology. Nanotechnology is used in information technology and electronics, in addition to the food industry. Working with little things and executing small processes is what nanotechnology is all about.

Atomic Force Microscopy (AFM) is a technique for applying force to an atom of matter in order to alter its properties and work. A microscope is a device that uses nanotechnology to apply a force to the atomic fraction of a sample matter. such as quantum dots, a nanoparticle used for optical detection of gene and protein in animals and cells assays, as well as tumour and lymph node visualisation, and nanowire, a nanostructure used for tumour and lymph node visualisation.

CONCLUSION

Nanotechnology is the study of nanoparticles; it is primarily for molecules and atoms of any matter. There are many different types of nanoparticles present, and each nanoparticle has a different industrial application. Among all the nanoparticles, one nanoparticle named cantilever has been discussed in this paper, as well as its application and output. Nanotechnology may be described as a technique for measuring, predicting, and building materials with various characteristics by manipulating or altering their atomic or molecular behavior on a nanoscale scale. Because atoms and molecules, which are groups of atoms, are very small in nature and their small size creates complexity in work, scientists and engineers are attempting to gain control of these small particles. They also take control of atoms and molecules individually, manipulating them to use with extraordinary precision. Nanotechnology has a wide range of applications in engineering, medicine, and industry because atomic control is a very excellent and effective instrument for the future. Nanotechnology has the ability to ignite and transform us from head to toe by implementing and bringing about a variety of complicated alterations. Many complicated and difficult interactions occur at a very tiny scale thanks to nanotechnology. Nanotechnology will impact the lives of virtually every person on the globe in the next several years if it continues to develop at its present pace, making it the biggest breakthrough in human history.

AN ANALYSIS OF PROTEOMICS AND ITS APPLICATIONS

Ms. Deepti Mathpal*

*SMAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: deepti.ips@sanskriti.edu.in

ABSTRACT

Proteomics is the study of the identification and measurement of total protein content in a cell, tissue, or organism using various methods. It works in tandem with other "omics" technologies like genomics and transcriptomics to determine the identification of an organism's proteins and to understand their structure and activities. Proteomics-based technologies are used in a variety of research settings, including the detection of various diagnostic markers, vaccine candidates, pathogenicity mechanisms, the alteration of expression patterns in response to various signals, and the interpretation of functional protein pathways in various diseases. Proteomics is very complicated since it entails analyzing and categorizing a genome's total protein signatures. Mass spectrometry, with LC–MS–MS and MALDI-TOF/TOF as common equipment, is at the heart of today's proteomics. However, the expenses of using proteomics facilities, such as software for equipment, databases, and the need for trained people, significantly rise, limiting their usage, particularly in poor countries. Furthermore, because of intricate regulatory mechanisms that regulate protein expression levels, the proteome is extremely dynamic. This study aims to explain the different proteomics methods, as well as their current advancements and applications in research and analysis.

KEYWORDS:*Amino Acid, Polypeptide, Protein, Proteomics.*

1. INTRODUCTION

Protein is a very complex molecule found in all living things. Amino acid polymers make up proteins. In 1902, Emil Fischer and Franz Hofmeister published a paper on proteins. Proteins serve a crucial part in metabolic processes. The sequence of particular amino acids transcribed by mRNA determines the primary structure of a protein, which guides the correct folding of the polypeptide chain into the secondary structure. The alpha helix, a portion of the polypeptide that folds into a corkscrew form, is one kind of secondary structure. Beta strands are polypeptide linear structures that link together to create a flat beta sheet. The final protein is formed when turns and coils interact chemically to produce the unique three-dimensional shape of the appropriate three-dimensional structure. Many proteins, on the other hand, are made up of several polypeptide subunits that combine to form the final active protein. The quaternary structure of these proteins is formed through interactions between the various subunits. One of

the most hopeful outcomes of research into human genes and proteins has been the discovery of possible novel medicines for illness therapy. To discover proteins linked to a disease, this method uses genome and proteome data[1].

The word "proteomics" was originally used in 1995 to describe the large-scale characterisation of a cell lines, tissues, or organisms complete protein complement. Proteomics is the study of proteins on a large scale, focusing on their composition, shapes, functions, and connections with the proteins that control cell activities2, 3. Proteomics is the primary topic of attention since it provides a greater knowledge of an organism than genomics. Genomics may provide an approximate estimate of a protein's expression. The majority of proteins work in tandem with other proteins, and one of the primary goals of proteomics is to determine which proteins interact. Proteomics is frequently seen as the next stage in the study of biological systems after genomics. It's considerably more difficult than genomics, owing to the fact that, although an organism's DNA remains relatively consistent throughout time, the entire protein expression profile varies with time, micro and macro environmental circumstances[2]. In forensic science, mass spectrometry (MS) has been extensively employed to identify substances, especially illegal narcotics. MS is a method for detecting substances that uses a mass spectrometer to separate ions based on their unique mass (mass-to-charge ratios). The technique works by assuming that each chemical has a distinct fragmentation pattern (mass spectrum). The sample is ionized, and the ions in it are sorted depending on their mass and relative abundance.

1.1 Types of Proteomics:

1.1.1 Expression proteomics:

Under two distinct circumstances, expression proteomics is utilized to investigate the qualitative and quantitative expression of total proteins. The protein that is accountable for the stress or sick condition, or the protein that is expressed owing to illness, may be compared between normal and treated or diseased cells. In most cases, expression proteomics investigations are used to look into the patterns of protein expression in aberrant cells. Ex. Differential protein expression may be evaluated by comparing tumor tissue samples to normal tissue samples. The protein expressional alterations, which are present and missing in tumor tissue as compared to normal tissue, were detected using 2-D gel electrophoresis and mass spectrometry techniques. Protein activities, multi-protein complexes, and signaling pathways may be used to determine which proteins are overexpressed and which are underexpressed. The discovery of these proteins will provide important knowledge about the molecular biology of tumor development and disease-specific ways to utilize these proteins as diagnostic markers or therapeutic targets[3].

1.1.2 Structural Proteomics:

Structural proteomics aids in the understanding of functional proteins' three-dimensional shape and structural complexities. When a protein's amino acid sequence is determined directly by sequencing or from the gene using a method called homology modelling, structural prediction is made. The structure and function of protein complexes found in a specific cellular organelle can be determined using structural proteomics. It is possible to identify all of the proteins present in a complex system, such as membranes, ribosomes, and cell organelles, as well as characterize all of the possible protein interactions between these proteins and protein complexes. For structure determination, various technologies such as X-ray crystallography and NMR spectroscopy were primarily used[4].

1.1.3 Functional Proteomics:

Understanding protein activities as well as unrevealing molecular processes inside the cell is explained by functional proteomics, which is dependent on the discovery of interacting protein partners. In fact, the interaction of an unknown protein with partners from a specific protein

complex engaged in a specific mechanism would strongly indicate its biological role. Furthermore, the in-vivo clarification of protein-protein interactions may significantly improve comprehensive descriptions of cellular signaling networks[5].

1.2 Techniques Involved In Proteomics:

To characterise protein structure and functions in proteomic study, both analytical and bioinformatics techniques were utilised. 2D gel electrophoresis and MALDI-TOF-MS were utilised as analytical methods. A variety of software programmes were utilised in the field of bioinformatics.

1.2.1 2-D Gel Electrophoresis:

Protein samples are resolved in 2-D gel electrophoresis based on charge in a process known as isoelectric focusing, and then by molecular weight in a second phase known as molecular weight focusing. The result is a picture made up of thousands of tiny dots, each of which represents a different protein. A good two-dimensional gel can resolve 1,000 to 2,000 protein spots, which appear as dots in the gel after staining. The method of 2-D gel electrophoresis is mostly used to analyze two comparable samples and identify particular protein differences[6].

1.2.2 2-D Electrophoresis Workflow Chart:

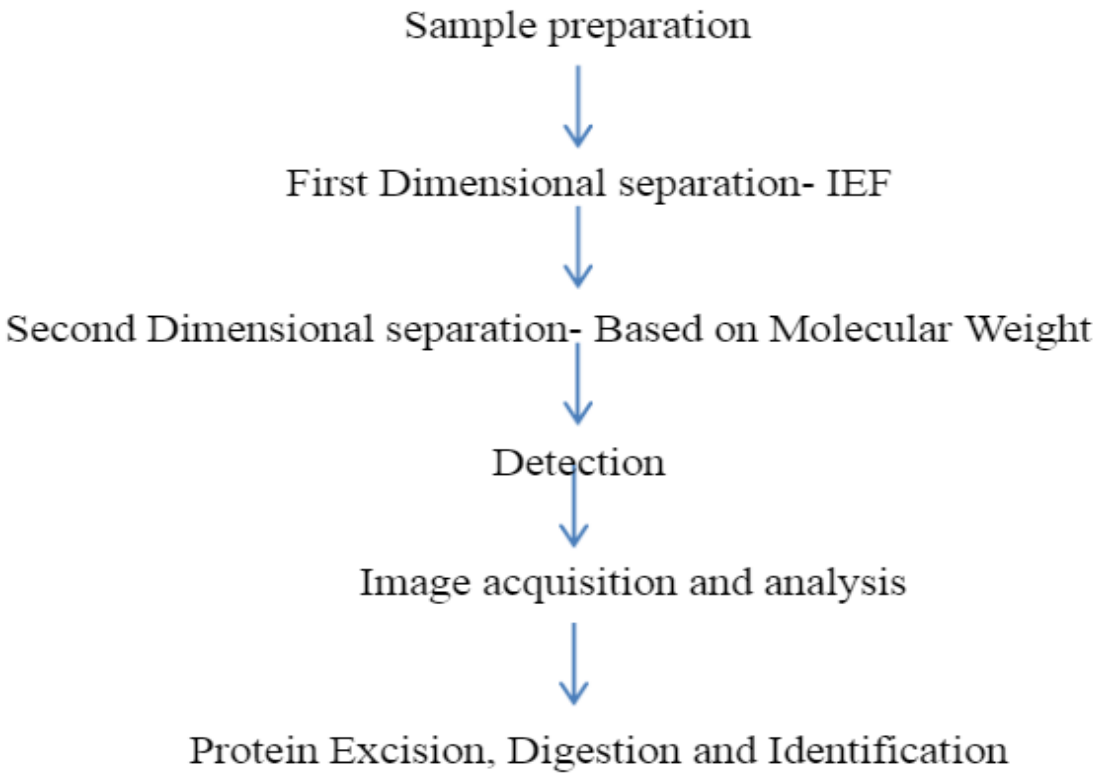

Figure 1: Representation of workflow chart of 2-D Electrophoresis.

Figure 1 represents workflow chart of 2-D Electrophoresis. Prepare the protein at an appropriate concentration and in a solution for IEF. Select a technique that preserves the natural charge, solubility, and relative abundance of your target proteins. IEF should be used to separate proteins based on their pI. For the required resolution and sample load, choose the suitable IPG strip length and pH gradient. Choose the best loading and separation parameters for your samples. SDS-PAGE is used to separate proteins based on their size. Choose the right size, composition, and separation conditions for your gel. Use a complete protein stain or fluorescent protein tags to see proteins. Select a staining method that is compatible with the sensitivity requirements and

imaging equipment available. Using suitable photographic equipment and software capture digital pictures of the 2-D designs. Then, using 2-D software, examine the patterns. Extraction of protein spots of interest from the gel, digestion of the proteins, and MS analysis of the digests.

1.2.3 MS Analysis:

Mass spectrometry is an analytical method that generates spectra of the masses of atoms or molecules in a material sample. The spectra are used to figure out a sample's elemental or isotopic signature, particle and molecule masses, and the chemical structures of molecules like peptides and other chemical compounds. Mass spectrometry measures the mass to charge ratios of charged molecules or molecule fragments generated by ionizing chemical substances. For protein identification, MALDI-TOF is the most effective method[7].

1.2.4 MALDI-TOF-MS:

Matrix Assisted Laser Desorption/Ionisation (MALDI) is a soft ionization method used in spectrometry to analyze biomolecules such as DNA, protein, and peptides. Because biomolecules and synthetic polymers have low volatility and are thermally fragile, the use of MS for characterisation has been restricted. The advent of MALDI-TOF MS, which allows for the mass determination of biomolecules by ionization and vaporization without degradation, as well as the use of a Laser beam to ionize the sample, has reduced these issues.

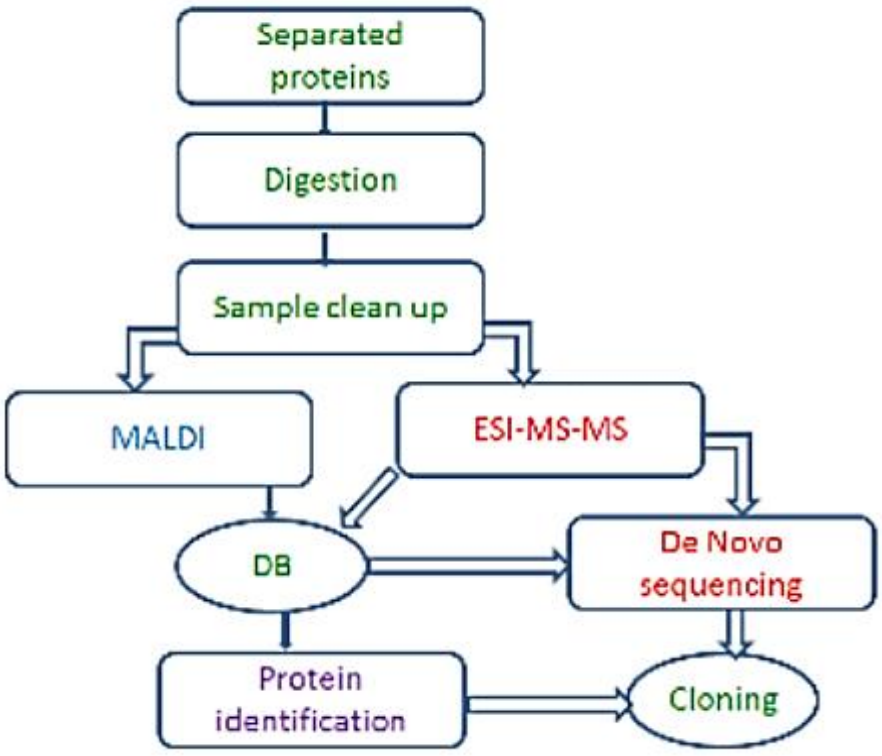

Figure 2: Representation of Matrix Assisted Laser Desorption/Ionisation (MALDI) analysis method[8]**.**

Peptide maps have been generated from protein samples that have been analyzed by HPLC or SDS PAGE. These peptide maps have been used to determine the purity of a known protein in a known sample or as fingerprints for proteins. When proteins are digested by proteolytic enzymes like trypsin, mass spectrometry creates a peptide map. This peptide map may be used to search a sequence database for a suitable match in the database that already exists.

1.2.5 Sample Preparation:

Biomolecules such as proteins, peptides, and polymers of organic substances are characterized by MALDI-TOF MS. The process of sample preparation for MALDI-TOF is both fascinating and crucial. Prior to MALDI-TOF analysis, purify the protein sample since it is more tolerant of sample contaminants, but contaminants may severely disrupt sample molecules' integration with developing matrix crystals. In a 1:2 ratio, the sample and matrix may be mixed. Different kinds of matrices are employed depending on the sample, some of which are 2-dimensional (4-hydroxy phenylazo benzoic acid, 2, 4, 6-trihydroxyacetophenone, 3-aminoquinolone, cinnamic acid, etc.). The protein sample is combined with matrix on a metal plate and MALDI-TOF analysis is performed using the dried droplet method. The matrices were combined to provide somewhat better results16. Standard metal plates should be utilized in small quantities. Hydrophilic sample anchors, on the other hand, are effective in generating small spots.

1.2.6 Matrix:

A good matrix should have the following characteristics: it should be able to absorb UV wavelengths of about 237 nm, be readily evacuated, and be able to transmit proton to sample molecules. The matrix's main function is to absorb energy from laser pulses and then transmit that energy to the sample, which may cause the material to vaporize. Typical MALDI matrix for protein samples consists of hydroxylated benzoic acid and cinnamic acid derivatives.

1.3 ADVANCED METHODS IN PROTEOMICS:

1.3.1 Isotope-Coded Affinity Tags (ICAT):

It is a quantitative proteomics technique that does not need the use of gels and depends on chemical labeling reagents. These chemical probes are made up of three main components: a specified amino acid side chain, an isotopically coded linker, and a tag for affinity separation of labeled proteins and peptides. For a quantitative comparison of two proteomes, one sample was labeled with isotopically light isotopes, while the other was labeled with isotopically heavy isotopes. Both samples were tagged using isotope-coded reagents. LC-MS is used to examine these peptides. Deuterium, 13C 18, was used as a tag. The method primarily relied on the relative measurement of proteins in two or more biological samples. The extra technique in ICAT- Visible tag is visible isotope-coded affinity tags, which enable the electrophoresis location of tagged peptides to be readily observed.

1.3.2 Isobaric Tags for Relative and Absolute Quantification (iTRAQ):

It is also a non-gel-based method for quantifying proteins called isobaric tags for relative and absolute quantification (iTRAQ). In proteomics, iTRAQ is used to investigate quantitative changes in the proteome19. 4-plex and 8-plex are chemicals that may be used to label all peptides from various samples based on covalent labeling of the N-terminus and side chain amines of peptides from protein digestions with tags of variable mass. Mass spectrometry MS/MS may be used to analyze the samples. For analyzing MS/MS spectra, several kinds of software are available.

1.3.3 Absolute Quantification (Aqua):

AQUA is a research group that looks at the absolute quantification of proteins and their modifications. Synthetic proteins may be prepared via covalent alterations. These changes are chemically similar to posttranslational modifications that occur spontaneously. These peptides are utilized in tandem mass spectrometers to measure post-translationally changed proteins following proteolysis.

1.3.4 ESI-Q-IT-MS:

The resolution of the Micro electrospray ionization (ESI)-Quadrupole ion trap (QIT) Time of Flight (TOF) mass spectrometer (MS) is excellent. Proteins are ionised in solution and have various charge states in ESI ionisation. Because proteins have a high charge state, their m/z measurements are usually less than 2000, and the TOF detector has extremely excellent mass accuracy in this scan range, utilizing ESI-QTOF analysis for protein mass determination offers a number of advantages. In ESI-QTOF, this results in more precise mass measurements for proteins.

1.3.5 SELDI-TOF-MS:

Surface-enhanced laser desorption/ionization (SELDI) is a mass spectrometry ionization technique that is used to analyze protein mixtures. SELDI is most often used with time-of-flight mass spectrometers to identify proteins in clinical samples; it may also be used to compare protein levels with and without illness to find biomarkers.

2. LITERATURE REVIEW

Bystrom C et al. discussed Proteomics in which they explained how Background Clinical proteomics has historically referred to studies that use technologies to quantify the abundance of hundreds or thousands of proteins in a single sample to try to find new biomarkers for illness diagnosis, prognosis, or therapeutic treatment. These studies started with protein electrophoresis, namely two-dimensional (2D) gel electrophoresis, and have progressed to processes that largely depend on mass spectrometry (MS). Clinical labs have developed quantitative assays for proteins in human samples using the processes established for discovery proteomics, which address many of the problems associated with protein quantification by immunoassay. Clinical research is evolving, and protein measures used in patient treatment are about to change dramatically. Content this chapter starts with an overview of clinical proteomics, with a focus on serum and plasma protein 2D gel electrophoresis. It then goes on to discuss MS-based discovery methods, such as data-dependent and data-independent acquisition. It concludes with a review of bottom-up and top-down targeted quantitative proteomic techniques as alternatives to immunoassays and Western blotting. Peptide selection, denaturation and digestion, peptide and protein enrichment, internal standards, and calibration are all given special consideration[6].

Kempenaers B et al. discussed Proteomics in behavioral ecology in which they explained how Proteomics is the study of a genome's protein complement with the goal of comprehending protein production, regulation, function, and relationships. Without prior knowledge of the nature of these molecules, expression proteomics provides an unbiased picture of the proteins possibly linked with or accountable for particular actions. Recent developments in mass spectrometry, bioinformatics, and genome sequencing have made proteomics accessible to non-model species research in a variety of scientific areas. n this review, we draw behavioral ecologists' attention to proteomic technologies and highlight the tremendous potential they provide for interdisciplinary research by highlighting the benefits of large-scale protein studies, suggesting research topics best addressed by this approach, and highlighting some of the techniques available for the identification and quantification of prokaryotes. We also demonstrate how proteomic methods may aid in the formulation and testing of ideas about the processes underlying behavior, as well as the development of experimental instruments that allow for behavior modification[9].

Sweetman G et al. discussed Quantitative mass spectrometry in proteomic in which they explained how one of the most essential, but also most difficult, technical challenges in proteomics is quantifying differences between two or more physiological states of a biological system. Mass-spectrometry-based quantification techniques have grown in popularity during the

last five years, in addition to the traditional methods of differential protein gel or blot staining by dyes and fluorophores. The majority of these techniques use differential stable isotope labeling to produce a unique mass tag that can be detected by a mass spectrometer while also serving as a foundation for measurement[10].

3. DISCUSSION

The study of proteins and their interactions in a cell is known as proteomics. With the completion of the Human Genome Project, the focus is turning to the human organism's protein complement. Proteomics is anticipated to provide improved disease indicators for diagnosis and treatment monitoring since it more precisely represents the dynamic state of a cell, tissue, or organism. Proteomics technologies, which allow for the worldwide identification and quantification of proteins, have opened up new possibilities and difficulties for those trying to better understand illnesses. To discover molecular markers of illnesses based on protein pathways and signaling cascades, high-throughput proteomics methods combined with sophisticated bioinformatics are widely utilized. Mass spectrometry is an essential technique for molecular and cellular biology and plays an important role in proteomics. While there is a lot of promise, there are still a lot of problems to overcome, such as mining low abundant proteins and integrating proteomics with genomes and metabolomics data. Proteomics, on the other hand, provides the basis for building and retrieving valuable information for biomedical research. A glimpse of current problems in proteomics technology is addressed in this study.

4. CONCLUSION

Proteomics has made a lot of progress in recent years. The technologies are quick, sensitive, and cover a larger portion of the proteome. Purification, analysis, characterisation, quantification, sequence and structural analysis, and bioinformatics analysis of a huge number of proteins in all kinds of eukaryotic and prokaryotic organisms have all been successful using a combination of these methods. The increased usage of proteomics methods has benefitted all areas connected to biological sciences. However, further research is needed to enhance the repeatability and efficacy of well-known proteomics techniques.

ABSTRACT

More than a century has passed since Tissier discovered that rods with a bifid shape bifidobacteria dominated the gut microbiota of healthy breast-fed babies, but were missing from formula-fed children suffering from diarrhoea, establishing the theory that they played a role in preserving health. Since then, a number of studies have backed up this claim, although they were initially poorly planned and controlled, and they encountered practical difficulties such as strain specificity of characteristics and probiotics' sluggish growth on substrates other than human milk.Probiotic bacteria have grown in popularity over the past two decades as a consequence of mounting scientific data demonstrating their positive effects on human health. As a consequence, they've been used in a variety of goods, with the food sector playing a key role in researching and marketing them. Probiotics have been used in a variety of goods, mostly fermented dairy foods, in this market. Given this tendency, and despite solid scientific evidence linking these microbes to a variety of health advantages, further study is required to establish them and assess their safety as well as nutritional elements. The aim of this article is to examine the existing research on the idea of probiotic bacteria and their potential beneficial qualities, with an emphasis on those found in food.

KEYWORDS:*Diarrhoea, Health, Lactose, Prebiotics, Probiotics.*

1. INTRODUCTION

The link between probiotics and health has a long history. They have successfully developed through time, with the most recent ones amassing more significant proof that probiotic bacteria may benefit human health[1]. These findings, along with rising consumer knowledge of the link between health and nutrition, have created an enabling climate for the creation of the functional food concept, which describes foods or food components that offer health benefits beyond their nutritional worth. The functional food industry is growing, particularly in Japan, its origin, with additional possibilities in Europe and the United States, and probiotics account for the majority of its goods in most countries. Improvement of intestinal health, alleviation of lactose intolerance symptoms, and decrease of the risk of different illnesses have all been reported as benefits of probiotic intake, and many well-characterized Lactobacilli and Bifidobacteria strains are available for human use . Despite the encouraging findings, the significance of probiotics in

human health, as well as the safety of their use, should be studied further, since our understanding of the qualities required for their functioning in the gut is incomplete[2].

1.1 Probiotics:

The name probiotic is derived from the Greek word probioticos, which means "life." However, the definition of probiotics has changed through time in tandem with the growing interest in the use of live bacterial supplements and advances in understanding their mechanisms of action. The term was first used to describe substances produced by one microorganism that stimulated the growth of others, but it was later expanded to include tissue extracts that stimulated microbial growth and animal feed supplements that benefit animals by contributing to the balance of their intestinal flora. Until recently, Fuller's definition was the most commonly used, and it helped to shape the probiotic idea in many ways: "probiotics are live microbial feed additives that benefit the host animal by enhancing microbial balance. The current definition is provided by the Food and Agriculture Organization of the United Nations World Health Organization, which defines probiotics as "live bacteria that bestow a health benefit on the host when supplied in sufficient quantities." In the context of food, the term may be tweaked to emphasize that microbes have a positive effect "when eaten in sufficient quantities as part of food[3].

Gibson and Rober- froid used the term prebiotics in 1995 to characterize dietary supplements that are nondigestible by the host but may have positive effects by selectively stimulating the development or activity of microorganisms in the gut. Prebiotic compounds are not 642nfavourab or absorbed in the gastrointestinal system, but they may be utilized as probiotic substrates, with nondigestible fructo-oligosaccharides being the most frequently used at the moment. Certain writers have referred to the combination of probiotics and prebiotics as conbiotics, while others have referred to it as symbiotics. Although prebiotics seem to have a function in health promotion, further research is needed to confirm this. In recent years, the term "functional food" has been used to describe foods that include components that provide health benefits in addition to their nutritional worth. Probiotics, for example, are examples of goods that include biologically active components that enhance health[4].

1.2 Microbial Species with Applications as Probiotics:

Taking their definition into account, the number of microbial species that may have probiotic characteristics is staggering.Only strains categorized as lactic acid bacteria are relevant in terms of nutrition, and among them, those belonging to the genera Lactococcus and Bifidobacterium have the most significant characteristics in a practical setting. Lactic acid bacteria are Gram-positive, catalase-negative bacteria that ferment carbohydrates to generate lactic acid as the primary end-product. Because they utilize a different metabolic route, the species Bifidobacterium is usually not phylogenetically classified among them. Streptococcus 642nfavourable and Lactococcuslactis, two of the most economically significant lactic acid bacteria, are two additional species that play a major role in the food business, especially dairy products, while not technically being called probiotics[5].

It's worth noting that, since probiotic actions are strain-dependent, strain identification is necessary to determine their eligibility and efficacy for industrial use. This is accomplished via a mix of phenotypic testing followed by molecular methods such as DNA/DNA hybridization, 16SRNA sequencing, and so on.

1.3 Desirable Probiotic Properties:

A prospective probiotic strain is anticipated to possess certain desired characteristics in order to exercise its positive effects. The ones currently determined by in vitro tests are I acid and bile tolerance, which appears to be crucial for oral administration, adhesion to mucosal and epithelial surfaces, an important property for successful immune modulation, competitive exclusion of

pathogens, and prevention of pathogen adhesion and colonisation,antimicrobial activity against pathogenic bacteria, antimicrobial activity against pathogenic bacteria, antimicrobial activity against path. Nonetheless, the significance of these metrics is still debatable due to issues of relevance, in vivo and in vitro differences, and a lack of uniformity of operating procedures. Because no one criterion is required for all probiotic uses, the best way to determine a strain's characteristics is to conduct research on a particular population and physiologic function[6].

The probiotic dosage levels in the final product should be based on those shown to be effective in human trials, and the colony forming units per gram of product is an essential metric. Although information on minimum effective concentrations is still lacking, it is widely accepted that probiotic products should contain at least 106 CFU/Ml or gram of probiotic microorganisms and that a total of 108 to 109 probiotic microorganisms should be consumed daily for the probiotic effect to be transferred to the consumer. Furthermore, the strains must be capable of growing in both manufacturing and commercial environments, as well as retaining viability under typical storage conditions. Viability is a requirement for probiotic activity since it enhances processes including adherence, gut permeability reduction, and immunomodulation, and it poses an industrial difficulty. However, other research have shown that viability is not required for all probiotic effects, since not all pathways or clinical advantages are directly linked to viability, and that even cell wall components on certain probiotic bacteria or probiotic DNA may have important health effects. Thus, for certain probiotic strains, excellent growth during the early manufacturing stages may be sufficient, and they may not need high storage viability[7].

1.4 Mechanisms of Probiotic Activity:

Probiotics have a variety of modes of action, but the precise mechanism by which they exert their effects is yet unknown. These include bacteriocin and short-chain fatty acid synthesis, gut Ph reduction, nutritional competition, and mucosal barrier function stimulation and immunomodulation. Probiotics affect many elements of the acquired and innate immune response by promoting phagocytosis and IgA production, changing T-cell responses, increasing Th1 responses, and attenuating Th2 responses, according to several studies.

1.5 Probiotics and Food Products:

Probiotic strains are found in a broad variety of food items, which is continuously expanding. The most popular dairy products on the market include fermented milks, cheese, ice cream, buttermilk, milk powder, and yogurts, with the latter accounting for the majority of sales.

As an appropriate method of probiotic administration to the customer, nondairy food applications include soy-based products, nutrition bars, cereals, and a range of juices. Aside from safety, the compatibility of the product with the microbe and the preservation of its viability during food processing, packaging, and storage conditions are also variables to consider when assessing the effectiveness of including probiotic strains into such goods. The Ph of a food, for example, influences the survival and development of the integrated probiotic, which is one of the reasons why soft cheeses seem to have a variety of benefits over yoghurt as delivery methods for viable probiotics to the gastrointestinal tract. Current technical developments provide new methods to solve probiotic stability and viability problems, opening up new possibilities for their integration into new media and, as a result, meeting rising consumer demand. Microencapsulation technologies have been created to shield microorganisms from the effects of the outside world. Beverage producers may now offer a dry version of the probiotic bacteria to consumers thanks to the development of a straw delivery method. Furthermore, live spores of a spore-forming probiotic are available on the market, which provide processing benefits. Simultaneously, the potential of bifidobacteria to produce lantibiotics (antimicrobial compounds) is being investigated for use in the food industry.

1.6 Hea1th Benefits of Probiotics:

Probiotics' claims of beneficial effects, such as improved gut health, improved immunological response, lower blood cholesterol, and cancer prevention, are gaining traction. These health properties are strain-specific and are influenced by the aforementioned mechanisms. While some of the health advantages have been well proven, others need further research to be confirmed. In fact, substantial evidence supports probiotic use in the treatment of acute diarrhoeal diseases, the prevention of antibiotic-associated diarrhoea, and the improvement of lactose metabolism, but insufficient evidence supports their use in other clinical conditions.

1.7 Antibiotic-Associated Diarrhoea:

Diarrhoea, mild or severe, is a frequent side effect of antibiotic treatment because the natural microbiota is inhibited, allowing opportunistic or pathogenic strains to thrive. Diarrhoea without mucosal abnormalities to pseudomembranous colitis are all possible symptoms. The latter is a severe kind of antibiotic-associated diarrhoea (produced by Clostridium difficile, which may produce lethal strains following antibiotic usage). The term comes from the plaque-like adherence of fibrinopurulent material to the injured mucosal layer, and it is characterized by diarrhoea, abdominal distention, vomiting, fever, and 644nfavourable, as well as consequences including toxic megacolon and perforation if left untreated. The treatment comprises of discontinuing the causative antibiotic, correcting electrolyte imbalances, and, in extreme instances, metronidazole or vancomycin therapy. Treatment using probiotics, such as L. rhamnosus and S. boulardii, has been utilized in clinical practice. Probiotic usage has been linked to a lower incidence of antibiotic-associated diarrhoea in many trials. Probiotic supplementation (specifically, L. rhamnosus, L. casei, and the yeast S. boulardii, since these are the probiotics most often included in the majority of studies) is linked with a decreased risk of antibiotic-induced diarrhoea, according to a recent meta-analysis. The optimum dosage of probiotic preparation and the comparative effectiveness of different probiotic treatments are topics for future study.

1.8 Infectious Diarrhoea:

Probiotic bacteria are perhaps best known for their use in the treatment and prevention of infectious diarrhoea. Rotavirus is the world's most frequent cause of acute infantile diarrhoea and a leading cause of newborn death. The virus replicates in the highly differentiated absorptive columnar cells of the small intestinal epithelium, and the normal microflora seems to play a key role in the host response to infection, since antigen absorption in germ-free mice is much higher than in normal animals. Probiotic addition of baby foods has been used to prevent rotavirus infections as well as to treat existing illness. Probiotics such as L. rhamnosus GG, L. reuteri, L. casei Shirota, and B. animalis Bb12 have been demonstrated in well-controlled clinical trials to reduce the duration of acute rotavirus diarrhoea, with the greatest evidence pointing to the effectiveness of L. rhamnosus GG and B. animalis Bb12. Competitive blockade of receptor site signals regulating secretory and motility 644nfavour, amplification of the immune response, and creation of chemicals that directly inactivate virus particles are among the suggested methods. There is evidence that some food and 644nfavour probiotic strains may limit the development and adherence of a variety of diarrhoeal disorders, in addition to rotavirus infection. Probiotics such as Lactobacillus reuteri, Lactobacillus rhamnosus GG, Lactobacillus casei, and S. boulardii have been shown to reduce the duration of acute diarrhoea in children. In a prospective, randomized, controlled French trial of children in day care, for example, the given probiotic yoghurt product containing L. casei substantially reduced the mean duration of diarrhoea compared to the traditional one [40]. Probiotics have been studied in the prevention of travellers' diarrhoea in adults in a number of trials. Despite the fact that findings are inconsistent owing to differences in research demographics, types of probiotics examined, dosages used, as well as trip

destination and 645nfavoura compliance, L. rhamnosus GG, S. boulardii, L. acidophilus, and B. bifidum seem to be effective. Furthermore, many animal studies have shown that probiotics have an inhibitory effect on enteropathogens, mostly via the formation of bacteriocins.

1.9 Lactose Intolerance:

Lactose intolerance is caused by a genetically programmed lack of beta-galactosidase, which prevents lactose from being infavourable into the monosaccharides glucose and galactose. When undigested lactose reaches the big intestine, bacterial enzymes breakdown it, causing osmotic diarrhoea. Beta-galactosidase deficiency may be acquired and is generally reversible. Other reasons include pelvic radiation, which destroys the mucosa, rotavirus infection, which infects lactase-producing cells, and short bowel syndrome. After consuming milk or milk products, lactose intolerant people experience diarrhoea, stomach discomfort, and flatulence. Although conventional yoghurt preparations containing S. infavourable and L. delbrueckii ssp. Bulgaricus are more effective in this regard, partly due to higher beta-galactosidase activity, lactose metabolism improvement is a claimed health benefit attributed to probiotics, and it appears to involve specific strains more than others and in specific concentrations. As a result, and since some people have reacted well to probiotic supplementation, doctors should explore it as a treatment option.

1.10 Probiotics and Allergy:

Recent research indicates that early life exposure to bacteria may protect against allergies, and in this case, probiotics may offer a safe alternative to microbial stimulation for babies' growing immune systems. At the same time, they enhance mucosal barrier function, which is thought to aid in the modulation of allergic responses. The importance of intestinal microbiota in allergy is confirmed by findings of quantitative and qualitative differences between children and babies with allergies and healthy children and infants, with the former showing colonization by a more adult-like type of microflora. Food allergies and atopic dermatitis seem to be especially affected by probiotic effects. The latter is a common chronic relapsing skin disease of children, with genetic predisposition as well as the individual's exposure to environmental allergens playing a role in its etiology. Only a few strains have been evaluated for their efficacy in the treatment and prevention of newborn allergy. B. lactis and L. rhamnosus GG were shown to be effective in reducing the severity of atopic eczema in a recent trial of breast-fed babies with atopic eczema. Furthermore, when given prenatally to women who had at least one first-degree relative with atopic eczema, allergic rhinitis, or asthma, L. rhamnosus GG was shown to be effective in avoiding the development of atopic eczema in high-risk babies. Probiotics, on the other hand, haven't proven particularly effective in reducing asthma symptoms. Food allergy is defined as an immunologically mediated 645 nfavourable response to dietary antigens, which results in subsequent intestinal inflammation and disruptions. The mechanisms of L. rhamnosus GG's immune modulating effect are unknown, although they seem to be linked to antigen transport through the intestinal mucosa. Probiotic preparations have recently been examined in people with milk hypersensitivity (not lactose intolerance), with the conclusion that some strains may reduce the milk-induced inflammatory response and ameliorate allergy symptoms; nevertheless, further research is needed in this area.

1.11 Other Health Benefits:

The list of health advantages mediated by probiotics is not limited to the ones described so far, but also contains a number of potential effects that need to be confirmed in human research. Probiotic bacteria are dietary components that may have a role in cancer prevention, according to research. Although the exact mechanisms are still being researched, studies have shown that certain Lactobacillus and Bifidobacterium spp. Reduce the levels of carcinogenetic enzymes produced by colonic flora by normalizing intestinal permeability and microflora balance, as well

as producing antimutagenic organic acids and enhancing the host's immune system. Furthermore, research indicates that probiotic bacteria-containing foods may help prevent coronary heart disease by lowering serum cholesterol levels and improving blood pressure management. Interference with cholesterol absorption from the stomach, direct cholesterol assimilation, and the formation of end fermentation products that affect systemic levels of blood lipids and mediate an antihypertensive effect are among the proposed processes. Nonetheless, these probiotic effects are still up for dispute, since further long-term human trials are required. Finally, probiotic strains found in dairy products have been demonstrated to enhance the treatment result in women with bacterial vaginosis, most likely by assisting the normal vaginal lactobacilli microbiota.

2. LITERATURE REVIEW

CastañedaGuillot C et al. discussed probiotics in aquaculture. The goal of this research is to provide complete information on the use of probiotics in aquaculture. Probiotics have been shown to aid in the growth, survival, and health of aquatic animals. In aquaculture, intestines, gills, aquatic animals' skin mucous, ecosystems, and even culture collections and commercial goods may be used to get suitable probiotics, which have been identified as bacteria (Gram-positive and Gram-negative) and nonbacterial species (bacteriophages, microalgae and yeasts). While a bacterium may be a disease to one aquatic animal, it may be beneficial to another; the screening procedure is important in determining which probiotic species to use. Probiotics are administered in a variety of ways, from the oral/water regimen to feed additives, the latter of which is widely employed in aquaculture. Probiotics may be used in single or multiple strains, as well as in conjunction with prebiotics, immunostimulants such synbiotics and synbiotism, and in both living and dead forms. To provide probiotics to aquatic animals, encapsulating probiotics with live feed is a viable option. Dosage and timing are important variables in achieving the intended outcomes. Probiotics have a variety of effects, some of which are well known and others that aren't[8].

Snydman D et al. discussed Risk and safety of probiotics in which they explained how for years, probiotics have been used safely. In published clinical studies, safety results are reported in a variety of ways. Although existing probiotic clinical trials show no indication of increased risk, the Agency for Healthcare Research and Quality stated in 2011 that "the present research is not well prepared to address concerns on the safety of probiotics in intervention studies with confidence." Critics argue that the overwhelming body of evidence, which includes a long history of safe probiotic usage, data from clinical trials, and animal and in vitro research, all support the premise that probiotics are usually safe for most people. Systemic infections, detrimental metabolic activities, excessive immunological activation in vulnerable people, gene transfer, and gastrointestinal side effects are among the theoretical hazards reported in case reports, clinical trial findings, and experimental models[9].

Balakrishnan K et al. discussed beneficial properties of probiotics in which they explained how Probiotics are living bacteria found in fermented foods and cultured milk, and are often utilized in baby meal preparation. They're known as "healthy bacteria" because they have a variety of health benefits, including preventing bowel illnesses, boosting the immune system, treating lactose intolerance and restoring gut microbial balance, alleviating menopause problems, and decreasing traveler's diarrhoea. Recent research has focused on their application in the treatment of skin and oral disorders. Furthermore, probiotics have been proposed as a new treatment option for anxiety and depression by modulating the gut-brain axis[10].

3. DISCUSSION

The human gut is home to a diverse population of microorganisms, mostly bacteria, that may have both negative and positive impacts on human health. The variety, composition, and stability

of the intestinal microbiota help to maintain intestinal homeostasis in healthy people. Changes in the human intestinal microbiota caused by lifestyle or dietary changes, as well as antibiotic exposure, may have a role in the development of metabolic illnesses and disorders. Because ingested bacteria may transiently integrate into the gut microbiome, probiotic intake has been suggested as a way to reduce these disruptions. Probiotics are living bacteria that, when eaten in appropriate quantities, help to maintain the gut microbiota's balance and stability. Several strains of Lactobacillus and Bifidobacterium are the most often utilized probiotics. This paper discusses several aspects of Probiotics.

4. CONCLUSION

There is scientific data that suggests including probiotics into one's diet may provide health advantages. When it comes to the prevention and treatment of some diseases, this data seems sufficient, but when it comes to others, it appears promising or even contentious. Bowel problems such as lactose intolerance, antibiotic-associated diarrhoea and infectious diarrhoea, and allergies are among the most well-documented effects, and new data is accumulating on their possible involvement in a variety of other illnesses. Such products are becoming more popular at the same time as relevant consumer knowledge is growing, and they tend to constitute one of the biggest functional food markets. Dairy products, especially yoghurt, remain the most significant vehicles for delivering probiotic bacteria to consumers, with the nondairy industry developing as well as a consequence of advancements in food technology and rising demand. As the variety of new goods with enhanced sensory appeal expands, customer acceptability grows, and the food sector spends more in this expanding market by developing new methods and products, creating a virtuous cycle. Nonetheless, probiotics for human use are still in their early stages of research. More study, in the form of controlled human trials, is required to identify which probiotics and doses are most effective for particular patients, as well as to show their safety and limits. Furthermore, probiotics' regulatory position as food components must be defined on an international level, with a focus on efficacy, safety, and the validation of health claims on food labels. There is no doubt that the role of probiotics in nutrition and medicine will grow significantly over the next decade, and while their use in the prevention and treatment of various disorders should be considered by medical professionals and promoted by the food industry, it should be done with caution and respect for the consumer.

ABSTRACT

Drawing geometry is a branch of geometry in which spatial figures consisting of points, lines, and the sum of surfaces are studied in terms of their flat images or projections. The main function of graphic geometry is to align a three-dimensional object with its flat projection model. Innovative methods of teaching descriptive geometry in higher education require modernization.

KEYWORDS:*Higher Professional Education, Professional Competence, Methodological Support, Descriptive Geometry and Engineering Graphics.*

INTRODUCTION

Recently, the leadership of our government has highlighted four key areas for further development of higher education. One of them is the abandonment of paperwork and the introduction of digital technologies. Training of technical specialists requires the transmission of large amounts of graphic data (drawings) over long distances. When it comes to descriptive geometry, diagrams should be sent in both directions: from student to teacher, and from student to student, pointing out shortcomings. The use of the remote method involves the dynamic exchange of information using computer networks instead of ordinary mail messages. In this regard, the problem of abandoning the study of paper engineering graphics and transferring project documents to computer media is a priority.

In this case, transferring graphic files prepared in AutoCAD on a computer is no problem, only the educational standards do not provide for the transfer of all images to the plane of computer graphics only. The basis of graphic geometry is the study of geometric figures in orthogonal projections, i.e. the properties of spatial shapes are studied directly from the drawing itself. In other words, the student has a flat image of the object being studied, not the originals. This is the greatest difficulty of the science under consideration. Thus, descriptive geometry serves as a theoretical basis for a drawing course, and a closely related course is based on knowledge of the basics of elementary geometry (planimetry and stereometry), so great attention is paid to these definitions and theorems of elementary geometry later used in descriptive geometry. should be

given. In this case, in particular, it is necessary to dwell on the method of geometric locations of points and lines.

Students should first be taught to solve problems in space, that is, to model a task with the power of spatial imagination. All the elements of the problem are in place, that is, only after the student sees his task in space, it will be possible to proceed to the representation of it in the plane using the methods of descriptive geometry. Particular attention is paid to the ability to correctly analyze the initial data of the problem, because the process of correct execution of the problem depends on the correctness of these analyzes.

The main guide for practical training in descriptive geometry is the "Workbook". It should be designed in a concise way so that students can implement the solutions directly in the workbook and do not spend extra time re-drawing the graphic state of the task. It also eliminates the possibility of making the wrong decision because the graphic situation is distorted during redrawing**.**

LITERATURE REVIEW

The use of specially designed models and real technical details, as well as the demonstration of Flash animations will give good results in mastering the course. It is advisable to use animation technology in the preparation of electronic guidelines. However, experience has shown that over-indulgence in models weakens independent spatial thinking [1]. It is advisable to use models only when students have problems. Each subject, including descriptive geometry, must develop an educational concept that affirms the essence of the subject and helps to identify approaches and teaching methods. While the method of teaching a topic is based on general didactics, this methodology represents a necessary source of didactics. There is an existing connection between didactics and methodology as there is between general and specific things. One of the main tasks of didactics is to reflect as deeply as possible the experience and generalizations existing in the methodology of teaching in these individual disciplines.

The methodology of higher education combines the scientific and educational bases, while the educational bases are always based on the scientific basis. Teaching methods are based on scientific content and methods. The scientific method allows us to evaluate what is possible and what is not possible in science. The methodological aspect of lecture teaching is based on the creative use of teaching theory. One of the main pedagogical requirements is that each lesson should be interesting and the listeners should have a deep understanding of the essence of the topic. Based on the goals and objectives of teaching, teaching methods can be considered as the construction of a didactic system and its activities to solve specific educational problems.

RESEARCH METHODOLOGY

Drawing geometry tasks range from simple learning tasks to identifying and solving original, design-practical problems. Problem-based learning requires students to do independent creative research.

For a long time, there were training systems that provided training materials and test assignments in the form of texts and images. Data in such systems has a linear or tree-like structure, modern systems use hypertext and multimedia tools, and remote work with the student is provided. Several e-learning manuals on descriptive geometry have been reviewed. The difference between them is mainly the location of the subjects and the quality of the pictorial material. We can mention the work [1] in which the problem of increasing visibility is posed and simple and effective imaging tools for solving problems of descriptive geometry are proposed. Later, systems emerged that allowed the solution to be performed graphically on a computer screen, in response to which the student would have to show one or more points of the drawing.

Also noteworthy is the e-learning system [3], which provides a comprehensive approach to the teaching of computer drawing and geometric modeling, and provides an interactive study of two-dimensional and spatial structures. Even in systems known as the Monge method of plane construction, objects of corresponding size are not formed.

The use of a training system that allows you to build drawings on the Monge apparatus and at the same time create three-dimensional images of objects and see the results in axonometry gives good results. The system can be used for user-controlled operation as well as in training mode. To create lessons, a special language is used that describes geometric shapes and the actions in them. Lessons can be formatted using a text editor as well as in user memorization mode. In this case, each process performed on the objects is related to one or more sentences of the language mentioned above. The introduction of computer technology in the educational process is of particular importance today. Human development is determined by the level of development of its productive forces and, above all, by the human intellect, certain requirements are placed on its formation, adequate perception and processing of information in a concentrated and time-limited environment, professional competence [4, 6].

ANALYSIS AND DISCUSSION OF RESULTS

The purpose of graphics training is to develop skills in elementary geometric devices, work in a graphic editor, geometric graphics, analysis of oral and visual information, projection graphics, and increase productivity in the creation of technical documentation [5] on machine graphics is to have the initial skills. In recent years, there has been a steady decline in the volume of sciences that develop spatial perception. The formation of geometric thinking should begin at a much younger age. There is inconsistency in the reform of primary, secondary and higher vocational education. As a result, it is felt that spatial perceptions are not developed among the students of the first two stages.

CONCLUSIONS AND SUGGESTIONS

The formation of spatial imagination skills begins with the study of elements of geometry, descriptive geometry, engineering, and computer graphics. The organizational principles of traditional teaching of spatial imagination are based on a relatively large workload. This approach justifies itself, but the regular reduction in the amount of time devoted to science leads to a significant decrease in the level of preparation.

The high rate of development of computer-aided design methods and tools has created an urgent need to study the pedagogical aspects of geometric modeling.

ABSTRACT

This article discusses one of the most pressing issues in the education system, namely the content of the lesson and the competencies that determine the quality of teaching.In addition, guidelines and recommendations have been developed for teachers to pay attention to the structure of the lesson, what is relevant to its content in the process of preparation for the lesson.

KEYWORDS:*Course, Competence, Scientific, Media, Didactic Materials, Attention, Course Stages.*

INTRODUCTION

One of the thinkers said of a lesson, "A good lesson for an hour is a great work."The student's knowledge, interest in science, ability to work with text, maps, tables, tools, as well as the teacher's knowledge of the materials in the curriculum, the ability to distinguish key ideas on the topic given to students in the process of explaining the topic, sequence, consistency, exhibition, skills and abilities to follow the principles of harmony of theory and practice, to pay attention to the plan in determining the purpose of the subject, to monitor and evaluate students 'knowledge in accordance with the requirements of the Regulations on monitoring and evaluation of students' knowledge in higher education institutions, to use time effectively during the lesson,

As shown above in the process of preparing a lesson If the competencies that determine the quality of the course are systematically applied, it is possible to increase the quality of teaching, to increase students' interest in science education.

Without knowing the essence of the concept of the lesson, talking about the lesson is "like a person bathing in a river without water." For this reason, we considered it appropriate to dwell in detail on the nature of the lesson below.

In some literatures, a lesson is defined as a form of teaching based on the material taught to students in order to acquire knowledge, skills, competencies, worldviews and ethical-aesthetic

ideas, while in others it is defined as a completed part of the educational process in terms of time and organization.

It is known that in the educational process solves the functions aimed at the goals of education and development.

Processes that cannot be accomplished in the classroom, in counseling, and in independent assignments, that is, in meeting the requirements of the curriculum and syllabus, in achieving the development of students' knowledge and outlook, take place only in the classroom.

The concept of lesson planning was first introduced to the science of pedagogy by the German scientist F. Herbort entered.

Lesson plan- is a brief description of the lesson, which reflects the topic of the lesson, its purpose, its course and forms of monitoring and evaluation of students' knowledge.

The concept of a lesson plan is introduced to a future teacher for the first time in a higher education institution while studying subjects such as "General Pedagogy" and "Teaching Methods".

We will focus on the following components of the lesson plan.

- expression of the subject of the lesson;

- the purpose of the lesson;

- eaching aids;

- the course of the lesson;

- homework description.

Lesson topic. The teacher gives students a brief and clear annotation about the lesson topic. The topic of the course should be relevant to the syllabus, which is not only indicated for reporting to the administration of the educational institution, but also is announced to students at the beginning of the lesson and is often written on the board before the lesson begins or indicated in the presentation of the lesson topic. Therefore, the subject of the lesson in the curriculum should be able to formulate the whole essence of the lesson, clearly and very briefly.

The methodological sciences have defined that the lesson will consist of three main

- Objectives.

- Educational;

- Educational;

- Developer;

Thus, the educational purpose of the lesson is the content of knowledge, skills and competencies that are formed and strengthened in the minds of students.

For educational purposes - the teacher should indicate the educational value of the study material being studied.

The developmental goal is to include facts, events, and the ability to critically evaluate and compare them to help students develop logical thinking.

It is known that when a teacher comes to class unprepared, he cannot fully convey the purpose of the lesson to students; uses interactive methods ineffectively; does not ensure active participation and independent work of students in the lesson; questions asked to reinforce a lesson or to assess

students' knowledge are not structured in a problematic way. As a result, the effectiveness of the course decreases, and the quality of teaching does not improve .Therefore, the preparation of the lesson in accordance with its structure is one of the important competency-based approaches to improving the quality of teaching in the educational process.

Therefore, below we will think about what it is important for the teacher to focus on in the process of preparing the lesson according to its structure.

In determining the purpose of the lesson - It is important to take into account the specifics of the topic, the level of competence of students in the study of the subject, the place of the topic among the topics, the purposeful expression of the topic, the delivery of the goal to students.

When creating a lesson plan -the lesson plan should be mapped to the set goal, the plans should be in a logical sequence and interconnected, the time should be allocated for the plan items, and the forms of teaching should not be left out.

In covering the course content -The content of the course should meet the requirements of the State Educational Standard, the topics should be reliable, complete, understandable, the scientific content of the material should be educational and career-oriented, the formation of new concepts to overcome difficulties in acquiring new knowledge.

In the methodology of teaching -the level of students' mastery of the subject materials is directly related to the methods used by the teacher. It is known that classes in higher education institutions are conducted in the form of lectures, practical classes, laboratory work, seminars. The teacher has a high level of speaking culture in the classroom; it is important to be able to use visual aids effectively, to work with diagrams or tables with laboratory equipment at a high level, and to have the skills and competencies.

The effectiveness of the methodology used in the course is determined by the extent to which students have mastered the subject materials.

To do this, the teacher must: make the right choice of methods, tools and techniques of teaching; correctly define the purpose of the lesson; at each stage of the lesson, apply the methods correctly; diversity of methods and techniques used; effective use of modern pedagogical and information technologies, visual aids, handouts and didactic materials; adherence to criteria for monitoring and evaluation of students' knowledge, skills and abilities.

In the teacher's communication with students – Given the importance of students' discipline and adherence to academic activities, the teacher should review the general preparation of the classroom, constantly monitor the attention and activity of students, their interest in science.

It is important to have a high level of pedagogical ethics, to speak in a clear, understandable language, to be able to create a good psychological environment in the classroom and to express only those ideas that are relevant to the topic of the lesson.

In assessing students' knowledge –Teachers must adhere to the quality of knowledge, skills and competencies acquired by students; solid and in-depth knowledge;

In the scientific nature of the subject -the teacher has a deep knowledge of the subject on a scientific basis, as well as the ability to accurately state scientific rules and definitions and to inculcate scientific terms in the minds of students; to take into account the specifics of education in the classroom; to enrich the textbook topics with additional literature; The laboratory, which is carried out by the student, should pay attention to the expediency of practical and independent work in the scientific direction, the connection of education in the process of describing a new topic.

In the didactics of the course:

1. The content of the lesson should be clearly stated and consistently reach the minds of students.
2. Conformity of the stated ideas to the principles of education.
3. The course should consist of developmental and problem-based learning.
4. The appropriateness of the use of visual aids, handouts, didactic materials and ICT in the presentation of the topic in the classroom.
5. The need to conduct experiments, laboratory and practical work with a clear goal.
6. Correctly focus on working with textbooks and additional literature and ensure that the issues are consistent with theory and practice.
7. Examples and issues related to theory and practice.
8. Attention to the fact that the lesson is conducted in a certain system leads to the solution of the quality indicator.

In general, in accordance with the above ideas, rules, instructions, recommendations, competencies, lesson preparation - the improvement of the quality of students' knowledge, the development of skills and competencies, imposes a responsibility on the teaching profession.

AN ANALYSIS OF OPTICAL FIBRE COMMUNICATION

Mr. Manoj Kumar Ojha*

*SOEIT, Sanskriti University, Mathura, Uttar Pradesh, India
Email Id-manoj@sanskriti.edu.in

ABSTRACT

Recently, optical fiber communication technology has advanced significantly, with continuous exploration of new technologies substantially enhancing communications capabilities in the conventional sense, resulting in the use of optical fiber communication technology in a wider context. Because optical communication system deployment is expensive and reconfiguration is often difficult or uneconomical, system experimentation and simulation have become necessary to anticipate and optimize system performance. This paper is about communication via optical fibers. High-bandwidth transmission can handle large quantities of data, which may be further enhanced by lowering fiber losses, increasing data rates and distances, and developing optical sources and detectors that are compatible with fibres. The article also discusses current developments in the field of fiber optic communication, as well as advancements in various fiber types and their characteristics, optical sources, detectors, system limits, and applications.

KEYWORDS: *Data, Information, Light Emitting Diode (Led), Opticalfibercommunication.*

1. INTRODUCTION

Fiber optics communication is a method of transmitting information such as data, video, and speech that is modulated with a pulse of light that acts as an electromagnetic carrier wave and is sent down a glass tube over a long distance with very little attenuation or loss. The concept of complete internal reflection is used to transmit this modulated pulse of light through the glass tube (TIR). A fiber channel, also known as a fiber optics communication link, is a technology that offers a point-to-point data connection between two locations. It includes a data transmitter with a laser diode or Light Emitting Diode (LED) that converts an electric signal to light, a transmission fiber through which the modulated light travels, and a receiver with a photo detector that converts light to an electric signal. Fiber optics were not widely accessible until 1970, when Corning Glass Works was able to manufacture a fiber with a 20dB/km loss. The attenuation of today's optical fibers varies from 0.5dB/km to 1000dB/km, depending on the optical fiber utilized. Since the first commercial installation of a fiber-optic system in 1977, the applications of optical fiber communications have grown at a fast pace. Optical fiber connections were first used by telephone companies to replace their outdated copper wire networks. Optical fiber is used by today's telephone companies as the backbone architecture and as the long-

distance link between municipal phone systems.Fiber optics are also being integrated into cable television networks by cable providers. Optical fiber has mostly replaced the trunk lines that link central offices[1].

1.1 Importance of Optical Fiber:

Fiber optics are a flexible conduit that can transport information in the same way that a copper wire can transmit electricity. They are used to light tiny things. Copper, on the other hand, only transmits a few million electrical pulses per second, while an optical fiber can carry up to 20 billion light pulses per second. This implies that phone, cable, and computer companies can manage massive data transfers at the same time, much more than traditional lines can handle. Because of the tremendous growth in data volume over the last 20 years, fiber optic cable was created. The current Internet and World Wide Web would not be feasible without fiber optic cable[2].

1.2 Advantages Of Optical Fiber Communication[3]:

- **Extremely High Bandwidth***:*Fiber provides more bandwidth than any other cable-based data transmission method.
- **Expanding Bandwidth Is Simple:**With many current versions of fiber optic cabling, additional equipment may be connected to the existing fiber line to offer significantly increased capacity over the initially placed fiber. Dense Wavelength Division Multiplexing, or DWDM, allows fiber optic cable to switch on and off different wavelengths of light traveling down the fiber at will. Fiber cable's two features allow dynamic network capacity allocation to accommodate data traffic surges and lulls.
- **Resistance to Electromagnetic Interference:**Because fiber is extremely resistant to electromagnetic interference, it has a very low rate of bit error. The transfer of data via fiber optics is practically noise-free.
- **Early Detection Of Cable Damage And Secure Transmissions:**Unlike traditional, electron-based transmissions, fiber provides an extremely secure transmission medium because there is no way to detect the data being transmitted by “listening in” to the electromagnetic energy “leaking” through the cable. Splices in the cable may be readily identified by continuously monitoring an optical network and precisely measuring the time it takes light to reflect down the fiber.
- High frequency signals transmitted via conventional coaxial cable lose half their strength after just a few hundred meters, while optical fibers lose the same amount of power after 15 kilometers or more. At extremely long distances, a repeater will be needed.
- Optical fiber has a transmission capacity of 10 GB/sec, while coaxial cable has a rate of 1 GB/sec.
- It has a lot of benefits over copper wires during installation because of its tiny size, low weight, and high flexibility.
- Because fiber optics have no electrical conductivity, no grounding or shielding is required.

- Electromagnetic interference sensitivity, such as when a telephone line loses part of its signal to another.
- Because fiber does not lose any light, the transmission is also secure and unaffected.
- The fiber is devoid of electrical impulses, thus it cannot shock or cause other dangers. This makes fibers acceptable for use in potentially explosive environments.
- It's simple to set up and compatible with digital technologies.
- The cable's lightness and compact size allow it to transport a high quantity of signals.

1.3 Disadvantages Of Fiber Optics[4]:

- **Fiber Optic Cabling Installation Prices Are Still Expensive:**Despite the fact that fiber installation costs are decreasing by as much as 60% per year, fiber optic cable installation costs are still high. Fiber is extending beyond its initial domain and primary use in the carrier backbone, going into the local loop and allowing subscriber and end user broadband access via technologies such as F Fiber to the Home, Premises, and PONs (Passive Optical Networks).
- **Special Test Equipment Is Often Needed:**Test equipment designed for classical electron-based networking is ineffective in a fiber optic network. In order to effectively test optical fiber, equipment such as an OTDR (Optical Time Domain Reflect meter) is necessary, as well as costly; specialist optical test equipment such as optical probes at most fiber endpoints and connection nexuses.
- **Physical Damage Susceptibility:**Fiber is a tiny and compact wire that is prone to being cut or damaged during installation or building operations. Railroad car derailments represent a major cable damage danger since railways often provide rights-of-way for fiber optic installation, and these incidents may interrupt service to huge groups of people because fiber optic cables can give enormous data transfer capabilities. As a result, when fiber optic cable is selected as the transmission medium, restoration, backup, and survival must all be considered[5].
- **Wildlife Damage To Fiber Optic Cables:** Many birds, for example, find the Kevlar reinforcement substance of fiber cable jackets especially attractive as nesting material, so they nibble at them to get a piece of it. Beavers and other rodents chew on exposed fiber optic cable to sharpen their teeth, while insects like ants want the plastic covering in their diet, thus they're often seen nibbling on it. Sharks have been known to chew on fiber optic cable when it is installed underwater, particularly at the repeating spots, causing damage. A plant known as the Christmas tree plant treats fiber optic cable like a tree root, wrapping itself around it so tightly that light impulses traveling down the fiber are suffocated.
- *Cost:* Despite the fact that sand, the raw material used to make optical fibers, is plentiful and inexpensive, optical fibers are nevertheless more costly per metre than copper. Although a single fiber can transport much more signals than a single copper cable, the long transmission lengths necessitate the use of fewer and more costly repeaters.
- **Fragility:** Optical fibers are more susceptible to breakage than electrical cables.

- **Chemically Influenced:**The glass may be influenced by a variety of substances, including hydrogen gas (a problem in underwater cables.)
- **Opaqueness:** Despite widespread military usage, most fibers are known to turn opaque when exposed to radiation.
- **Requires Specialized Expertise:**Optical fiber cannot be connected as simply as copper wire, necessitating extra staff training as well as costly precision splicing and measuring equipment.
- Care should be taken while connecting fiber optic cables since if the connection is incorrect, a lot of attenuation will result in a long wave length.
- Because fiber optics has no electrical conductivity, the power supply to the repeaters is provided via copper wire rather than optical fiber.
- In comparison to other kinds of T/N lines, the installation cost is extremely expensive.

1.4 Applications Of Fiber Optics[6]:

Optical fibers' popularity is growing, and so are their applications and practical usage. Fiber optic cables have grown in popularity across a wide range of industries and applications.

1.4.1 Communications / Data Storage:

Fiber optics has made major advancements in the area of communications due to its resistance to electrical noise. The use of light as a data transmission medium has enhanced voice communication sound quality. It's also utilized for sending and receiving information.

1.4.2 Military:

Optical technologies provide more security than conventional metal-based systems. Magnetic interference enables information to leak via coaxial wires. Because fiber optics is impervious to electrical interference, it is ideal for military and communications applications where signal quality and data transfer security are critical. Because of the military's increasing interest in this technology, stronger fibers, specifically engineered cables, and high-quality components have been developed. It was also used in a wide range of applications, including seismic and sonar hydrophones, airplanes, submarines, and other underwater applications.

1.4.3 Medical:

Fiber optics are utilized as surgical lasers, light guides, and imaging instruments. Fiber optic cable is also used in endoscopes, which are diagnostic instruments that allow users to look through tiny holes in the body. For minimally invasive surgical operations, medical endoscopes are utilized. Bronchoscopes (for the lungs) and laparoscopes both utilize fiber optics. Endoscopes are all designed to appear like a long thin tube with a lens or camera at one end, through which light is emitted from a bundle of optical fibers tied together within the enclosure.

1.4.4 Mechanical or Industrial:

Industrial endoscopes also known as bore scopes or fiberscopes, allow the user to examine places that are difficult to access or view under normal conditions, such as jet engine interiors, mechanical welds in pipes and engines, space shuttles and rockets, and sewage lines and pipes.

1.4.5 Networking:

In a number of network setups, fiber optics is utilized to link servers and consumers. It improves data transmission speed, quality, and accuracy. The increased transmission of digital data via optical fibers has advanced computer and Internet technologies.

1.4.6 Industrial/Commercial:

Fiber optics is utilized for imaging in difficult-to-reach locations. It's also utilized in wiring when there's an issue with electromagnetic interference (EMI). It is often used as a sensory device to detect temperature, pressure, and other variables, as well as in the wiring of automobiles and industrial environments.

1.4.7 Spectroscopy:

Optical fiber bundles are used to transport light from a spectrometer to a material that cannot be put within the spectrometer so that its composition may be determined. By bouncing light off and through substances, a spectrometer can analyze them. A spectrometer may examine things that are too big to fit within, as well as gases and reactions that occur in pressure vessels, by utilizing optical fibers[7].

1.4.8 Broadcast/CATV /Cable Television:

Fiber optic cables are used by broadcast and cable providers to connect CATV, HDTV, the internet, video, and other applications. Fiber optic cable was first used in the cable television business in 1976, and its usage rapidly expanded due to its superiority over conventional coaxial wire. Fiber optic systems have become more affordable and capable of delivering crisper signals from a greater distance away from the source signal. It also cut down on signal losses and the number of amplifiers needed for each client. Because just one optical line is required for every 500 homes, fiber optic cable enables cable companies to deliver better service.

1.4.9 Lighting and Imaging:

Fiber optic cables are employed as sensors to detect and monitor a wide variety of factors, as well as for lighting and images. It's also utilized in medical, technical, and industrial research, development, and testing. In medical and other applications where strong light must beam on a target without a clear "line-of-sight route," fiber optics is utilized as light guides. Optical fibers are employed in certain buildings to carry sunlight from the roof to other sections of the structure. Decorative uses for optical fiber lighting include signage, art, and artificial Christmas trees. The light-transmitting concrete building product LiTraCon, which is a transparent concrete building material, requires optical fiber.

2. LITERATURE REVIEW

Arumugam M et al. discussed Optical fiber communication in which the article examines the evolution of optical communication technologies through time, as well as its early failures. The various generations of optical fiber communication, as well as their characteristics, are then examined. Total internal reflection is discussed, as well as various kinds of fibers and their sizes and refractive index profiles, dispersion, and loss processes. Finally, the overall optical fiber communication system is briefly discussed, along with its benefits and drawbacks. Future optical fiber communication based on soliton is also emphasized[8].

Satish Addanki et al. discussed optical fibers in which they discussed how Optical fibers may be used in light transmission applications since they are waveguides. The core of the optical fiber is surrounded by a glass or plastic layer termed cladding, which has a lower refractive index than the core. For the fine confinement of light inside the waveguide, the total internal reflection phenomenon is required. Optical fibers are classified primarily by their structure, number of modes, refractive index profile, dispersion, data processing capability, and polarization. The first three main kinds of optical fibers are the subject of this study. Fiber lasers may be used to produce and magnify a narrow concentrated beam of coherent and monochromatic light, which is a typical use of the fibers. The preform formation is one of three steps in the fabrication of optical fiber. The modified chemical vapor deposition (MCVD) method is a well-known method for fabricating optical fibers. Optical fiber sensors are widely used in optics and photonics for a variety of purposes. Optical biosensors based on refractive index shifts, which are extensively utilized for detecting biomolecules in their natural forms, may be produced as a sensing application[9].

Singh K discussed Optical Fibre Communication in which he discussed how Recently, optical fiber communication technology has advanced significantly, with continuous exploration of new technologies substantially enhancing communications capabilities in the conventional sense, resulting in the use of optical fiber communication technology in a wider context. Because optical communication system deployment is expensive and reconfiguration is often difficult or uneconomical, system experimentation and simulation have become essential for predicting and optimizing system performance. The topic of this article is optical fiber communication. High-bandwidth transmission can handle large quantities of data, which may be further enhanced by lowering fiber losses, increasing data rates and distances, and developing optical sources and detectors that are compatible with fibres. The article also discusses current developments in the field of fiber optic communication, as well as advancements in various fiber kinds and their characteristics, optical sources, detectors, system limits, and applications[10].

3. DISCUSSION

This article gives an overview of the most recent research and development in the area of fiber optic communication systems. In the past decade, there have been significant advancements in the area of optical fiber communication. Wide-bandwidth signal transmission with low latency is becoming more important in a variety of applications, including future exaflop-scale supercomputer development, finance algorithmic trading, and cloud computing. Optical fibres offer unrivaled transmission capacity, and they are currently the transmission medium of choice in telecommunications networks for long-distance and high-bit-rate transmission.

The primary goal of this article is to provide an overview of recent fiber optic communication research and development. Fiber optics is a critical component of the telecommunications infrastructure. It is suitable for gigabit transmission and beyond because to its high bandwidth capacity and low attenuation properties. The many kinds of fiber and their uses, light sources and detectors, couplers, splitters, wavelength-division multiplexers, and state-of-the-art technologies utilized in the most recent high-bandwidth communication systems have all been discussed. Because fiber-optic biosensors can be easily miniaturized and integrated for the determination of different target compounds in a wide variety of application fields, such as industrial process and environmental monitoring, food processing, and clinical applications, they will play a significant

role in the development of biosensors. Various fiber optic applications that have recently been created have been addressed. The fiber optics business has grown at a breakneck pace during the last five years. According to analysts, this sector will continue to expand at a rapid pace far into the next decade and beyond.

4. CONCLUSION

Optical fiber communications have transformed our lives in many ways over the past four decades, and low-loss optical transmission fibers have been essential to optical communications technology's tremendous success. Low-loss optical transmission fibers have unquestionably contributed to the tremendous success of optical communications technology. The so-called passive optical network was suggested for the already-envisioned fiber-to-the-home (FTTH) network in the telecommunications industry. The usage of passive optical splitters was extensively used in this network. Standard single-mode fibers were used to make these splitters (SMFs). Despite the fact that FTTH would not become widely available until decades later, research into the usage of components in telecommunications applications persisted. Optical fiber communications were transformed when the fiber optic amplifier became commercially available in the early 1990s. Optical signals might reach hundreds of kilometers without regeneration if they were amplified [1]. The signal-to-noise ratio (SNR) of the received signal and the available bandwidth are the two factors that ultimately restrict the performance of any communication system. The notion of channel capacity, developed within the context of information theory, may be used to express this restriction more explicitly.

Traditional copper wires twistedpair cable or coaxial cable have been replaced by fiber optic technology, which is a significant technical advancement. As we progress in the Information Technology era, the burden of transferring massive quantities of data must rest on this new technology's shoulders. There is no denying the enormous possibilities that fiber optic technology offers, and it should be continually studied and developed to meet future needs.

AN ANALYSIS OF HUMANOID ROBOT

Ms Anuska Sharma*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: anushka@sanskriti.edu.in

ABSTRACT

Exoskeleton technology has gone a long way since its inception in the late 1960s, thanks to advances in robotics. Exoskeleton designs have been created by researchers all over the globe, and some of the most well-known exoskeletons include the BLEEX, MIT exoskeleton, HAL, LOPES, ALEX, and many more. Although technology has progressed since the 1960s, there are still difficulties in exoskeleton design. In this research, we'll look at various exoskeleton technologies and their applications in rehabilitation. Based on a plethora of studies, this goal in rehabilitation seems to be promising.Humanoid robots, inspired by human looks and talents have become indispensable in human civilization in order to enhance people's quality of life. Many researchers have worked on humanoid robots to improve their capabilities all around the globe. Humanoid robot systems, in general, comprise decision-making and information-processing processes. Fuzzy sets are most frequently employed because of the uncertainty involved in decision-making and information processing. This research looks at a thorough literature analysis on humanoid robots that covers current technical advancements as well as ideas regarding fuzzy set models. The fundamental ideas and notions of fuzzy sets are given for humanoid robots.

KEYWORDS:*Exoskeleton, Human, Humanoid Robot, Sensors, Technology.*

1. INTRODUCTION

A humanoid robot is a programmed machine that can mimic human behaviours as well as appearance. A humanoid robot has two primary functions: the capacity to get information from its environment and the ability to perform physical tasks like moving or manipulating things. After years of research and development, the existing humanoid robots currently come in a variety of sizes, weights, and heights, all of which are linked to their intended use. Humanoid robots, in general, behave like humans, moving their eyes and lips to convey emotion. They also have hands and legs, allowing them to do a variety of human-like activities, as well as the capacity to learn new things via the use of sensors and other technologies like as artificial intelligence. In a nutshell, a humanoid robot is one that is equipped with sensors to detect its surroundings and effectors to carry out an action[1].

1.1 Architecture of Robot:

A humanoid robot is a machine that looks and acts like a person. A humanoid robot should have the appearance and behavior of a person. With the development of technology, the look and characteristics of humanoid robots are becoming more and more human-like. The technology being developed to make the humanoid robot appear like a person in terms of facial expressive robot head, robot hand, robot mobility, and robot learning behavior is discussed in the following subsections[2].

1.1.1 Facially expressive robot head:

Humanoid robot research focuses on the interaction between humans and robots. The capacity to communicate is always the most essential aspect of a humanoid robot's ability to behave like a person. We constantly communicate to one other via facial expressions, arm and hand movements, voice, and other body language in our everyday human-to-human contact. These acts are simple for humans to do and have been practiced from infancy. When it comes to human-robot communication, we want the robot to do what we do. As a result, some researchers began developing a humanoid robot capable of imitating human behavior.

The capacity to convey emotions in the face is one of the most significant characteristics of humans. Expression defines a person's personal characteristic and enhances communication efficiency in everyday human conversation. We've always hoped to be able to converse with robots in a human-like manner. As a result, face expressive robotic head systems, such as Character Robot Face (CRF), have been created by researchers. WE3RV, a human-like head robot, was created in Japan. Human emotions like pleasure and rage are defined and programmed into the robot. When the robot detects external stimuli using sensors, the data is translated, and the robot expresses emotion by moving the various elements of the face, such as the eyebrows, ears, eyelids, lips, and mouth, in a human-like manner. For example, a robot named Kismet was created in Cambridge and is capable of performing a range of proto-social reactions utilizing CCD camera technology and displaying human-like emotions[3].

The greatest problem is that a humanoid robot's expression coverage is insufficient. For example, human pleasure may be split into many distinct levels, each of which has its own expression, and the technology of human-like head robots is progressing to the point where the expression coverage will be comparable to human. Gazing is an essential part of human-to-human communication. A speaker uses it to communicate with his or her audience as a gaze pattern that may convey the speaker's mood. Eye contact is a rude or dominating indication where individuals will stare at each other in order to show respect while conversing. As a result, researchers are considering including the capacity to gaze in the robot. For Honda's humanoid robot, ASIMO, for example, the researcher developed a gaze and gesture algorithm. As a result, the ASIMO can look at humans and make hand movements, and it is regarded as a story-telling robot. A humanoid robot's gaze control entails detecting fixation points and coordinating head-eye motions. As the eyes of the humanoid robot, a camera is utilized. The robot's head will move in response to the identified item[4].

1.1.2 Robot hand:

The hand is one of the most essential organs in a human's everyday activities. Humans cannot easily accomplish tasks without the use of their hands. This is also used to a humanoid robot, resulting in a humanoid robot with hands. The human hand is a complicated mechanism whose performance and characteristics are difficult to duplicate. The weight, size, minimum number of fingers, necessary degrees of freedom (df) of the fingers, and others are key features of an artificial hand that mimics a human hand for a humanoid robot. The anthropomorphic artificial hand has been developed based on the key features that provide the fundamental function to the

hand, which is typically powered by DC motors. Fingers on a human hand may execute a variety of functions. Humans have been given the ability to manipulate their fingers since they were born. However, for a humanoid robot, executing the action in order to carry out duties such as stably pinching paper or needle with finger tips is very challenging. For high-performance remote manipulation, a robot with four fingers, each with three degrees of freedom, has been created. The manipulation method, on the other hand, is still in the early stages of development. In Japan, researchers created a robot hand that can pinch up paper. The terminal fingers now have more degrees of freedom of independent motion, while the thumb now has more degrees of freedom of twisting motion[5].

1.1.3 Robot Locomotion:

Walking by legs is simple for a human. However, adding it to a humanoid robot is a difficult job. Bipedal locomotion technique is used by today's humanoid robots. In the area of bipedal walking, there are now two methods, one of which is the Zero-Moment-Point hypothesis (ZMP). The location on the ground where the net moment of the inertial and gravitational forces has no component along the axes parallel to the ground is known as the ZMP. ZMP's trajectory is crucial in keeping the robots balanced when walking. The ZMP trajectory must be inside the supporting polygon specified by the position and forms of the supporting feet for a viable walking pattern. Asimo from Honda and the WABIAN bipedal humanoid robot created in Japan are only two examples of humanoid robots that use ZMP-based control. QRIO, a humanoid robot created in Japan, is another example. It is capable of sprinting and leaping in addition to walking. To accomplish steady run and leap, the researchers utilized the ZMP stability criteria. It showed that using this technology, the humanoid robot's movements is more human-like. The passive dynamic walking technique, which McGeer pioneered, is another option. Without the use of motors or controls, the humanoid robot can walk down a hill. The robot's energy efficiency is greater when this technique is used. The foot contact sensors make it simple to operate. However, owing to the round feet employed, this technology has certain limitations, such as the inability to stay still, the difficulty to start or stop walking, and the inability to alter the pace and direction. As a result, certain enhancements have been made, such as the addition of actuators to walking robots and the installation of direct drive or elastic actuators at parts of the biped's joints[6].

1.1.4 Robot Learning Behavior:

Face expressions and hand movements are used by a humanoid robot to interact with humans. It can even carry objects and travel from one location to another using its hand. However, in our everyday activities, all of these capabilities are insufficient; the humanoid robot must be able to modify current capabilities, deal with changes, and rapidly acquire new talents. Some methods, such as imitation learning, may be used on the humanoid robot to meet the criterion. When a third party shows a move, imitation learning involves instantly repeating it and storing it in memory. The external motion capture system, which is based on specific sensors, is used for humanoid robots. There are indicators that are used to detect movement. It may be difficult for a humanoid robot to mimic human behaviors at times. Some human movements, for example, cannot be replicated by the robot owing to joint angle restrictions, dynamic constraints, or a lack of joints. Another comparable approach is referred to as "programming by demonstration." This method enables the robot to watch a person doing a task. The material from the demonstration is then extracted and mapped into an abstract[7].

Reinforcement learning is another technique that improves the learning behavior of humanoid robots. A humanoid robot may use this technique to enhance its performance on sequential decision-making tasks. The robot's behavior will be enhanced as a result of this approach, since the time-consuming step-by-step programming will be removed. Several techniques, such as

reinforcement learning using Decision Trees, have been included into this methodology. During model learning, this approach will be aggressively generalized, reducing the number of trials needed for learning. Many research have used a discrete low-dimensional state space to perform reinforcement learning tasks. However, in order to operate the humanoid robot smoothly, a continuous high-dimensional state space should be used. In order to overcome the issue, the researcher developed the Allocation/Elimination Gaussian Soft max Basis Function Network (AE-GSBFN) technique for adaptive allocation[8].

1.2 Applications:

Humanoid robot development progresses on a regular basis. Previously, humanoid robots were primarily employed in domestic settings and for amusement. However, because to technological advancements, the humanoid robot may now be used in a variety of areas, including healthcare, sports, space exploration, construction and manufacturing, and even education. The following sections go through the many uses of humanoid robots in various areas.

1.2.1 Home applications:

In this day and age, individuals are preoccupied with their jobs and often leave their homes empty. As a result, they need a robot to care after their home while they are away. As a result, Japanese researchers created a system that allows people to operate one or more humanoid robots in their homes remotely using a mobile phone or the internet. This aids users in perceiving the circumstances at the robot's location. While the home is vacant, users may pre-define certain places in the house and delegate specific activities to the robot, allowing the humanoid robot to go to those spots and do chores depending on the user's requirements

1.2.2 Entertainment:

Humanoid robots are becoming more popular as entertainment devices. Humanoid robots communicate well with humans through facial expressions, hand gestures, and other body languages. Many humanoid robots are now being created for entertainment purposes. SDR-4X, a tiny humanoid robot, is one of the examples. It is capable of walking on an uneven surface and avoiding obstacles while walking in a real-world home setting. The dynamic and fluid dancing of the SDR-4X performance is composed using a program called SDR Motion Creator. Dancing and A Cappella Chorus performances are two of SDR-4X's major capabilities. SDR-4X can also learn and recognize the user's faces and names, as well as communicate with them using a synthetic voice.

1.2.3 Healthcare:

Humanoid robots have human-like characteristics, such as the ability to walk on two legs and interact with humans. Humanoid robots may be employed as service robots in hospitals to aid nurses and patients with their tasks, as well as to enable individuals in distant locations interact with those in the hospital. Humanoid robots have become the nurse's avatar in hospitals since they can speak and comprehend the patient's wants. For patients, a humanoid robot assists those who are unable to move. The patient may also converse with the robot and consider it as an additional user. One of the most common developmental diseases is autism. Many children with autism may struggle with everyday tasks such as communication, social engagement, and imaginative play. Robots may be utilized as a therapeutic aid in this case. There are two kinds of humanoid robots that have been specifically designed to assist youngsters with autism. IROMEC and KASPAR are the two humanoid robots. IROMEC is a mobile robotic platform featuring a cartoon-like figure as its interface. KASPAR is a humanoid robot with a tiny size. Both humanoid robots teach social interaction and communication skills to youngsters with autism.

1.2.4 Sport:

Sport is another significant human activity. As a result, experts are looking into the potential of a humanoid robot participating in sports. In the Robocup soccer tournament, fast and flexible walking is an essential requirement for a humanoid robot. The primary difficulty in doing so is the insecurity. To address this issue, the researcher developed a novel fuzzy-logic control system that allows the robot to walk quickly and easily while maintaining high turning stability. This may be accomplished via incline walking and carefully adjusting the step length. A fuzzy algorithm is used to determine the correct angle of the joint, allowing the robot to respond appropriately to different body circumstances. EFuRIO, a humanoid robot, was created for this purpose. The current version (third generation) is capable of standing, walking, turning, and kicking.

1.2.5 Construction And Industry:

It is critical to replace people with humanoid robots for hazardous work on the construction site. Construction machinery and equipment, for example, play an essential part in a variety of activities on the job site. Humans are often exposed to hazards when working machinery and equipment. If a humanoid robot can operate machinery and equipment while being controlled from a distant location, the issue of hazardous occupations will be solved. In a disaster scene, when a construction equipment is needed to take away some large and heavy items, a humanoid robot also performs an essential role. Working at a disaster scene is hazardous for a human operator. HRP-1 is a humanoid robot that was created in Japan by researchers. It uses tele-operation to use the proxy drives of construction equipment like a lift truck. This humanoid robot can be controlled by a command received from a remote computer. The humanoid robot's ability to handle and carry large items is limited. The majority of humanoid robots can only land at the position of their end-effectors. If the humanoid robot can make random contacts with the environment, it will be able to handle and carry larger items. As a result, the researcher suggested a technique called "full body contact motion." The contact status is controlled by the controller's distributed tactile sensors. The humanoid robot can now lift a 30 kg box using haptic input thanks to this technology.

1.2.6 Education:

In addition to the aforementioned uses, several researchers have begun to focus on education. Robotis, a Korean robot company, has created a humanoid robot named Bioloid. Bioloid is a hobbyist and educational robot kit designed to function as a teaching assistant and offer students with an interactive learning environment. In addition, the researcher suggested an IDML tool for instructors to use to create instructional materials and design the movements of the humanoid robot. Furthermore, IDML technologies offer a platform for students to engage with a humanoid robot and participate in learning activities. Bioloid, the educational robot, has a positive impact on kids and is able to hold their attention in class.

2. LITERATURE REVIEW

Sasaki K et al. discussed Repeatable Folding Task by Humanoid Robot Worker Using Deep Learning in which the suggested method collects data in an understandable manner and has the following features: task performing capacity, task reiteration ability, generalizability, and ease of application. The suggested method employs a real-time user interface with a monitor and a head-mounted display to give a first-person view. Teleoperation is utilized via this interface to gather task operating data, particularly for activities that are difficult to do using traditional methods. The suggested method also employs a two-phase deep learning model. A fully connected deep time delay neural network learns the dynamics of a robot task process from the extracted picture features and motion angle data, and a deep convolutional autoencoder recovers and reconstructs

images. The suggested model is evaluated using the 'Nextage Open' humanoid robot as an experimental platform. To evaluate the item folding task, 35 trained and 5 untrained sensory motor sequences were used. The object folding task is completed with a success rate of 77.8% when the trained model is tested using online generation[2].

Ogawa K et al. discussed Honda humanoid robots development in which The study began with the first prototype two-legged robot walking straight and still. The newest humanoid robot ASIMO has now accomplished a seamless transition from walking in a straight line to turning. ASIMO is Honda's most sophisticated robot in terms of mechanism and control system to date. The configuration of ASIMO enables it to function freely in human living spaces. With its five-finger arms and walking abilities, it may be of practical use to humans. The goal of ASIMO's future development is to create a robot that will enhance human civilization[9].

Khoramshahi M et al. discussed Humanoid robots versus humans in which they explained howHumanoid robots playing a therapeutic role in assisting people with social problems like autism is a novel area that has yet to be investigated in schizophrenia. We wanted to see how schizophrenia patients identify positive and negative facial expressions exhibited by a humanoid robot since the capacity for robots to communicate emotion seems to be crucial for human-robot interactions. There were 21 schizophrenia outpatients and 17 healthy people in the study. They were given pictures of human faces and a humanoid robot (iCub) exhibiting positive or negative emotions, as well as a non-social stimulus, in a response time test. The symptomatology, mental perception, response speed, and number of correct answers of the patients were all assessed. The results showed that patients and controls identified the emotional valence of human facial expressions better and quicker than the robot[10].

3. DISCUSSION

The researchers have achieved an amazing outcome after many years of study on humanoid robots. The researchers' contribution to the world's tremendous achievement ranges from a robot that only performed task-by-task setup by humans to a robot that can speak with humans, from a robot with just a gripper and roller to move and do work to a robot with hands and legs that are human-like. But, regardless of how much money is spent on research and development or how quickly technology advances, when will humanoid robots be commonplace in society? This is a huge problem that the whole globe is dealing with. However, this will not deter continued development into humanoid robots, and it is expected that they will become commonplace in the future. However, it is unclear how long the procedure will take. Humanoid robots are anticipated to have improved perceptual abilities in the future. To cope with the uncertainties of sensory signals, more sophisticated techniques will be created. The capacity of a humanoid robot to converse with humans will increase as computer vision and voice recognition technologies develop. Muscle-like actuators will be used in the mechanical components for safe operation of humanoid robots in close proximity to humans. The movement of the humanoid robot's hand, particularly the finger, will become smoother, similar to that of a human hand. Furthermore, humanoid robots will have a wider range of uses. For example, the development of an underwater humanoid robot may replace humans who suffer mobility and respiratory issues while venturing further into the sea . All of the aforementioned problems will be future research challenges for scholars.

4. CONCLUSION

With its capacity to gather information from its surroundings and perform physical tasks similar to humans, humanoid robots are a fascinating area of research. The basic idea of a humanoid robot is to collect information using various types of sensors and then execute various tasks based on that information utilizing the face expressive head, hands, torso, and legs. The research

of humanoid robots has been going on for almost four decades, and new technologies are being developed all the time to replace or improve previous ones. Many studies are influenced by science fiction films and programs such as "Star Wars," "Real Steel," and "Transformers." Humanoid robots that have recently been created are coming closer and closer to mimicking human behavior. The ASIMO by Honda, an astronaut-like robot, the HRP-4 by Kawada, a thin, quick, and sophisticated robot created by the Japanese government, and Nao by Aldebaran, one of the prettiest and most intelligent robots, are just a few of the popular humanoid robots. These humanoid robots are all behaving humanoid.

The current methods and technologies utilized by researchers, such as human-robot communication, hand and ocomotion systems, and learning behavior technology, have all been described and explored in this paper. In the past, humanoid robots were created for show rather than for a specific function or application. Humanoid robots have begun to be used in a variety of areas as technology has advanced in recent years, as described in this research. All of the created robots, however, are still in the research phase and will not be used in the actual world. The humanoid robot's future trend and difficulties are addressed. Humanoid robots will provide us with a higher quality and more pleasant existence if the difficulties stated can be overcome.

A BRIEF REVIEW ON THE SMART HOME AUTOMATION WITHTHE SOLAR DETECTOR

Ms. Shikha Parashar*

*SBAS, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: shikha.soet@sanskriti.edu.in

ABSTRACT

Everything is getting more mechanized as a result of technological advancements. With advancements in automation technology, a user's or anybody else's life is becoming easier in every way. Because automated systems are easier to use, everyone prefers them over manually run ones. The internet of things is abbreviated as IOT. This research study is divided into two sections. The solar panel on the roof and the motion detection light switching system in the room are the first two components. A stepper motor is used to drive the solar panel, which is controlled by a microprocessor. To absorb the most energy, the solar panel will constantly face the sum at a perpendicular angle. A signal may be transmitted from here to the room light switching system to turn on or off the light based on the quantity of solar radiation present outside, or by monitoring the stepper motor angle, i.e. sending a signal when the angle exceeds a certain degree. The second part consists of a PIR (passive infrared) sensor that detects motion in a room and is controlled by a microcontroller; when it detects human presence in the room, it will turn on the light; when it detects no human presence in the room, it will turn off the light after a threshold time limit. The time restriction may be anything between 10 and 20 minutes, depending on your instincts.

INTRODUCTION

A solar panel is a collection that allows a payload to be oriented toward the Sun. Solar panels, parabola troughs, Fresnel mirrors, lenses, and heliostat mirrors are common payloads. Devices are used in flat-panel solar systems to reduce the angle of incidence of sunlight as well as a photovoltaic panel, also known as the cosine error. When this angle is reduced, the quantity of energy generated from a given amount of fixed power generation capacity rises. Trackers were expected to be utilized in at least 85 percent of commercial installations larger than one megawatt from 2009 to 2012 in conventional solar applications in 2008-2009.

Home automation refers to working at home and its applications via the internet; the internet of things, meanwhile, has a wide range of uses and applications in engineering disciplines such as electrical, electronics, and computer science. Home automation is also becoming more useful in many ways, and this is good in use because of its safety and security. Home automation and controllers have expanded the area of home automation[1].

Home automation has also progressed and become more helpful in a variety of areas and aspects since it aids in the monitoring and control of all home appliances according to the needs of the user. Home automation systems have evolved into energy-efficient and user-friendly smart home technologies. Automation has also been utilized in offices for the same reason, as well as for accurate and real-time data on work and workers[2].

There are many characteristics in home automation that distinguish it from other technologies. For example, it has fundamental functions to preserve the user's pleasure and comfort, as well as it works intelligently to warn for any problem. In this article, a system is created that is controlled by an AVR controller and is used to turn on and off the applicant's appliances and home automation. This embedded system includes an AVR microcontroller, a mobile phone, a led bulb for alerting, a stepper motor, a solar panel for storing energy, a battery for storing energy, a rectifier for converting ac to dc, an inverter for converting dc to ac, and a ldr sensor for sensing light intensity[3].

1. Home Automation:

Home automation is a one-of-a-kind system that can control and interact with almost every item in your house, including fans, led lights, bulbs, air conditioners, and refrigerators. The term "home automation" refers to the integration of all household components and equipment. For example, a centralized microcontroller panel may handle everything from heating and air conditioning to security systems, lighting, and electrical appliances in general[4].

Home automation includes things like remotely controlling parts of our house with a computer or mobile device, programming electrical items to react automatically to certain circumstances or scenarios, and centralizing the management of a variety of appliances in our home into a single control center. For example, we can control all of the lights in and around our house from a single location, eliminating the need to leave or go downstairs if we forget to turn off or on any appliances[5].

IOT stands for internet of things;IoT gives us ideas about how the things and physical objects connected with sensors and software or with any other technologies as shown in the Figure 1. The Internet of things helps in data exchange and works accordingly.

Figure 1: IOT in which the Physical Objects Connected With Sensors and Software.

Stepper Motor is used to provide discrete steps of motion to the device by which it is connected. In a stepper motor we can adjust the speed of the stepper motor as shown in the Figure 2. Application of stepper motors is in various places such as motor is used to provide precise position to the device, and in hard disk drives, robotics, antennas, telescopes and some toys[4].

Stepper Motor is used to provide discrete steps of motion to the device by which it is connected. In a stepper motor we can adjust the speed of the stepper motor. Application of stepper motors is in various places such as motor is used to provide precise position to the device, and in hard disk drives, robotics, antennas, telescopes and some toys. The Figure 3 shows home automation using Arduino.

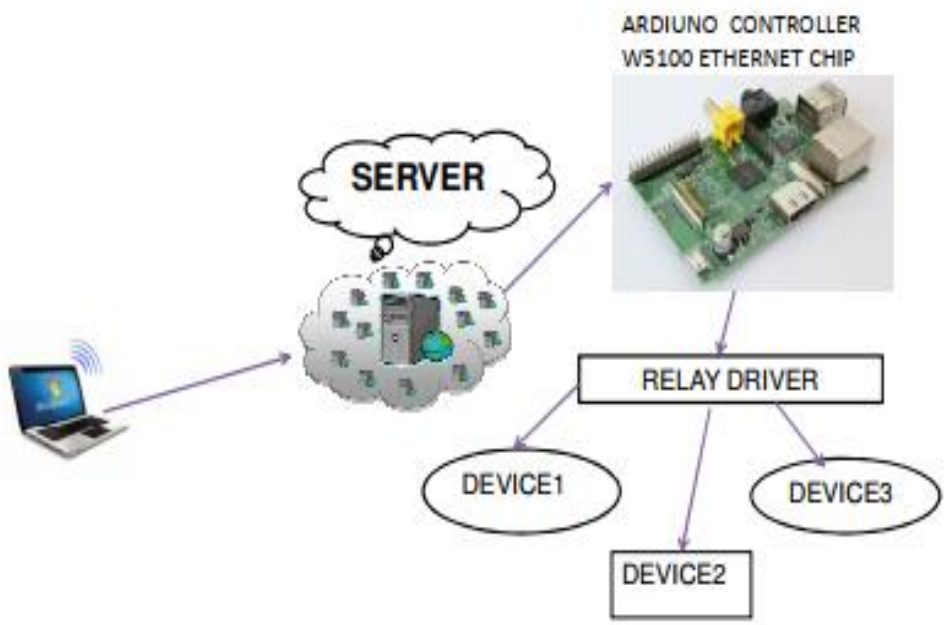

Figure 3: Home Automation using the Arduino

The phrase "home automation" refers to the coordination of all household entities and equipment. A centrally controlled microcontroller panel, for example, may manage anything from heating and air conditioning to security systems, lights, and electrical appliances in general[7][8].

LITERATURE REVIEW

A Review Paper on Home Automation by Nikita Baidya, Prem Kumar S discussed what is home automation in which he discussed that home automation refers to a certain function that may be used to control and build an online connection between home appliances. The phrase "home automation" refers to the coordination of all household entities and equipment.

A centrally controlled microcontroller panel, for example, may manage anything from heating and air conditioning to security systems, lights, and electrical appliances in general. In this paper, examples of automation are discussed, including the implementation of the internet of things for home automation, a bluetooth-based wireless home automation system using an FPGA, hand gesture-based home automation for the visually impaired, and home automation using an atmega328 microcontroller and Android [9].

There have been some main controllers used to control many automated processes whether in the home, office, or any other industry, some main controllers such as the Arduino uno board, which is very useful and most popular controller in the industry, Arduino uno interfaces shows and explains an Interface, which is the method by which home automation controller attracts with user requirements. Touch Panels, Keypads, Remotes, Mobile Devices, and the Internet are all examples of interfaces. The control technique utilized by the controller is also explained in this article, which includes a controller, interfaces to communicate with the controller, and sensors that inform the controller about what is going on in the home.

This article also examined the Wi-Fi module and its benefits and drawbacks, presented a block diagram of the Wi-Fi module and its application, and explained how we may use Wi-Fi in our everyday life. The term "integrated circuit" refers to a circuit that is utilized in a variety of electronic applications. In this article, the ULN IC has been described, as well as the use of the IC and its benefits and drawbacks[10].

Satish Palaniappan, Naveen Hariharan, Naren T Kesh, Vidhyalakshmi S, Angel Deborah S discussed GSM based home automation in a research paper titled Home Automation Systems - A Study, in which he discussed system which is discussed in this paper provides three ways to control the GSM based home automation, in which he discussed system which is discussed in this paper provides three ways to control the GSM based home automation, in the control technique utilized by the controller is also explained in this article, which includes a controller, interfaces to communicate with the controller, and sensors that inform the controller about what is going on in the home. Home automation can be done with different controllers in this paper explains the bluetooth base home automation, explain phone based home automation in which explains that some systems are described as an enabling system that can be used to provide a common framework for home automation in which explains that some systems are described as an enabling system that can be used to provide a common framework for home automation in which explains that some systems are described as an enabling system that can be used to provide a common framework for home automation in which explains that It offers a smart home system with features including a system controller, housewide wiring, and a single interface.

This will allow the current system to be used for home automation. This article discusses ZigBee-based home automation and displays a block design of the transmission unit, as well as the wireless communication system and block diagrams of the transmitter and reception sections. This article also discusses various mixed type controllers that are utilized for home automation. And it describes what remote control HAS been and how it works.

Kusuma S M addressed house automation using the internet of things in a study paper titled Home Automation Using Internet of Things by Vinay sagar K N, and the advantages of the internet of things in everyday and industrial life. Making the procedure simple and quick, as well as describing the whole process and components connected to home automation, is what home automation and office automation, or any other automation, entails[11].

DISCUSSION

This research paper has two main parts: the solar panel on the roof and the motion detection light switching system in the room. Smart home automation with solar tracker is used in this research paper, which helps in making home smartly automated and different controllers and motors are used to run solar panels in an effective manner. A stepper motor is used to drive the solar panel, which is controlled by a microprocessor. To absorb the most energy, the solar panel will constantly face the sum at a perpendicular angle. A signal may be transmitted from here to the room light switching system to turn on or off the light based on the quantity of solar radiation present outside, or by monitoring the stepper motor angle, i.e. sending a signal when the angle exceeds a certain degree. The second part consists of a PIR (passive infrared) sensor that detects motion in a room and is controlled by a microcontroller; when it detects human presence in the room, it will turn on the light; when it detects no human presence in the room, it will turn off the

light after a threshold time limit. In this paper, the energy absorbed by the solar panel is then stored in a battery, which is dc power, and this dc power is then supplied to the bulb and fan. However, some appliances require ac power, so we must convert absorbed dc power to ac power using an inverter, and a rectifier is installed to convert dc power to ac power. It also reduces energy consumption, resulting in lower power bills, and it enhances security while also increasing our home's comfort level. There have been numerous applications that are based on IoT or any other controller that makes that system smart and automated, thus this article addressed what should be an ideal system of home automation with remote access, taking care of all of those tasks.

CONCLUSION

In this century, the internet has become very important, and many applications have been working on the internet of things. The world is crowded with mobile phone users, and Android has become the most popular and successful mobile device. It is also very flexible in terms of adding new functions, and it has evolved into an open and growing source that can run any advancement technology. The human brain is very creative when it comes to thinking, and mobile apps are utilized to help people think more creatively. This article addressed home automation utilizing a solar tracker, with the process controlled by an AVR microcontroller. This allows us to manage and control our homes intelligently, as well as conserve energy and build such a system at a low cost. There are many benefits to putting such systems in the home, including the ability to decrease energy costs, flexibility, and security. It also reduces energy consumption, resulting in lower power bills, and it enhances security while also increasing our home's comfort level. There have been numerous applications that are based on IoT or any other controller that makes that system smart and automated, thus this article addressed what should be an ideal system of home automation with remote access, taking care of all of those tasks. This article describes what an ideal system is and how it should operate in real time, as well as providing real-time data to users that wish to view the update. Also, describe what a GSM system is and how it may assist with home automation. A GSM system has one data channel that is utilized to offer internet connectivity. The Internet is becoming faster and more popular. In addition, many tasks are dependent on the internet provider; the internet enables equipment to utilize the internet of things and its functions. A web application with a mobile application should be used as the user interface. In order for individuals of all sorts to have access to the system.

A STATISTICAL ANALYSIS OF THE EFFECTS OF WATER CONTAMINATION ON RURAL AREAS

Prof Meenakshi Sharma*

*Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Emailid: osd@sanskriti.edu.in

ABSTRACT

The economic consequences of industrial water contamination in rural areas are assessed in terms of losses to agricultural output, human health, and animals in this study. The cost estimates are based on comprehensive primary (household level) data gathered from an exhaustive study of two villages in Andhra Pradesh, South India–one a pollution-stricken village and the other a control village (not impacted by pollution). The cost calculations showed that industrial pollution has a significant monetary effect on rural areas. The compensation concept, according to the study, may work if damage estimates are reasonable. Furthermore, just enacting laws and establishing administrative structures are essential but insufficient to solve environmental issues. Policies must be applied in the proper context. Institutions should be robust enough to cope with the issues at hand, with greater autonomy and capabilities.

KEYWORDS:*Andhra Pradesh,Contamination, Costs, Environment, Rural Communities, South India, Water Pollution.*

1. INTRODUCTION

Water quality is an essential component of water resources that has received little attention. While fast industrialization in developing nations has aided economic growth, it has also resulted in significant economic losses due to adverse impacts on agricultural operations, human health, and the environment as a whole due to air and water pollution. Water contamination, in general, is a significant problem because of its effect on a wide range of economic activities. In the setting of an agricultural economy like India, the issue of water pollution takes on more significance. While the problem's scope is modest and widely dispersed, the losses incurred as a result of its effect are significant. Despite the fact that there has been many empirical research on agricultural-related environmental issues such as soil deterioration, wind and water erosion, only a few studies have focused on industrial pollution and its effect on agriculture and other industries. Though few researchers calculated the costs of environmental degradation in terms of human health, soil erosion, deforestation, and other factors at the macro level, the bulk of the indicators are unrelated to industrial pollution. Damage costs in poor nations have been demonstrated to be greater than in developed ones[1]. Environmental costs in poor nations were estimated to be about 5% of GDP, according to their calculations. In industrialized nations, a few

studies have looked at the effect of industrial pollution on agriculture, human health, and ecosystems. According to few researchers, the most significant and immediate effects of environmental deterioration in the poor countries are harm to human health. In Chongqing, one of China's severely polluted megacities, scientists attempted to quantify the effect of industrial pollution on agricultural, human health, and industrial activity. The overall expenses of industrial pollution were projected to be 1.2 percent of Chongqing's gross domestic product. The agricultural sector accounts for 56% of the total, while human capital and the industrial sector account for 20% and 18%, respectively[2]. These studies show that industrial pollution has a significant impact on other economic sectors. In recent years, India has attempted to quantify the different effects of industrial pollution and sewage on human health, agriculture and livestock, and other economic sectors. Most of these studies, however, make estimations based on a single reference point. They haven't taken into consideration changes over time or compared the impacted circumstances to those in a control group[3]. This research aims to provide a comprehensive assessment of the costs of industrial pollution on different elements of rural lives. In the context of policy development, such an approach is critical. Furthermore, the study area offers a unique chance to analyze policy dynamics owing to the active participation of civil society, the court, and other stakeholders in the problem-solving process. As a result, governmental interventions to address the issues have previously been attempted in the study area, albeit with little effectiveness. In reality, when local communities protested, a judicial committee conducted an investigation and came up with a compensation plan for rural households, which was rejected. This research would aid us in deciphering the reasons behind the policy's failure. This study attempts to calculate the costs of industrial pollution, focusing on the environmental effect of water contamination on rural populations in general, and agricultural productivity, human health, and animals in particular. The following are some of the most important issues in this regard: (a) links between industrial development and changes in the micro (local) environment, (b) pollution-related damage to crops, livestock, and human health in rural communities, and (c) understanding the reasons for policy failure in addressing the problem. These problems are investigated in depth using primary (household level) data gathered during an extensive study of two villages in the industrial belt surrounding Hyderabad, Andhra Pradesh's capital city—one a pollution-stricken village and the other a control village (not impacted by pollution). Various illnesses caused by water contamination have afflicted the whole hamlet of Kazipalle (polluted village). Skin infection, tooth corrosion, joint discomfort, lack of appetite, faulty eyesight, fever, stomach pain, respiratory illnesses, diarrhea, and other water-borne ailments are common in the contaminated hamlet. In addition, the community has seen overall physical weakness, immature development, and persistent cold and cough in the middle aged and youngsters. Lung infections, fever, and joint discomfort are the most common symptoms. There have been instances when the family's main source of income has been afflicted by severe illnesses, causing the family's economic situation to deteriorate. Though individuals do not drink contaminated water directly, they are exposed to harmful chemical water when working on farms, bathing, washing clothing, and eating, particularly milk and vegetables. When comparing vegetables produced in arsenic-contaminated water to those grown in uncontaminated water, greater arsenic levels were observed, ranging from 9% to 1000 percent depending on the kind of crop. Arsenic poisoning has also been linked to severe health issues, including stillbirths[4].In both the afflicted and control villages, Table 5 shows the proportion of households reporting the frequency of incidence of different illnesses throughout the size classes. Following the advent of pollution in Kazipalle, almost all types of farmers are experiencing joint discomfort and fever. In contrast to the scenario before pollution, the incidence of joint discomfort, skin problems, fever, and stomach ache among medium-sized farmers is very significant. The majority of patients (60%) experienced daily joint pain, with 40 percent reporting skin, fever, and stomach discomfort on a weekly basis. Similarly, everyday joint

discomfort was reported by 95 percent of small farmers and 86 percent of marginal farmers, respectively. After pollution, 63 percent and 72 percent of small and marginal farmers experienced monthly fever. Because of increased exposure, variations in ethylating capacity across people and groups, micro-environment and nutrition, and other factors, the poor are disproportionately impacted. Only fever was the most common complaint across all categories of farmers in the control village, with monthly and annual frequency. The most striking aspect of the pollution-related health issue is that women are the ones who suffer the most . In each family, the proportion of afflicted females is greater. This is because women frequently perform all of the domestic chores with polluted water, such as washing, nursing infants, and so on. Even in the control village, this is true, particularly in the marginal farmer group, where approximately 80% of the women complained of or reported different illnesses. This may be linked to tainted water from the village's tube well (groundwater). They perform all of their home chores using water from the community tube well, which is contaminated[5] . Aside from that, the average number of days unwell and unable to work per family per year in the polluted village is much greater than in the non-polluted village. The difference between the number of days sick and not available for work in both villages before and after pollution is the number of days lost due to pollution.

2. DISCUSSION

The impacts on production approach concept say that an activity's influence on the environment may affect a producer's output, costs, and profitability. If there is a market for goods and services, the value of the change in production, such as the decreased value of fish caught as a consequence of river pollution, may be used to reflect the impacts of environmental impact. EOP has also been used to track the effect of environmental changes on agriculture, forestry, fisheries, electricity, public services, and other sectors, such as soil erosion, deforestation, wetland and reef damage, and air and water pollution. The effect of water pollution (irrigation water) on agricultural production and yearly household losses has been evaluated in our research using real current market prices. Costs of replacement (RC): The replacement cost (RC) method argues that if the environment has already been harmed, it will cost money to restore it to its previous condition. Victims of environmental degradation, for example, replace their environment by relocating away from the afflicted region. The expenses that victims suffer as a result of relocating to a clean environment are referred to as replacement costs. Direct monitoring of actual expenditure on protections against environmental hazards is one of the methods used in the replacement cost method. The replacement cost approach is utilized in this research to evaluate the damage costs of pump sets caused by water contamination. The data on damage costs is based on the actual expenditure of families on repairs and replacements. Human resources (HC): People are seen as economic capital under the human capital concept, and their earnings are treated as a return on investment. Environmental economics is concerned with the impact of poor environmental conditions on human health and the implications for people and society's productive capacity[6]. In this case, the approach would calculate the economic costs of a productive human being being sick. When calculating the economic costs of sickness caused by environmental variables, two variations may be considered: first, the loss of wages (working days) due to illness, and second, the expense of medical care. We estimated the loss of productive time and yearly health-care spending in our research, and then came up with the overall economic loss owing to sickness. It should be emphasized, however, that we did not use medical research or epidemiological evidence to link the disease to pollution. However, laboratory studies of different water samples from the hamlet strongly indicate that there are significant risks of water-borne illnesses. WHO have shown links between water contaminants including arsenic and other metals and health risks? The connection between water contamination and the prevalent illnesses in the communities was also confirmed during our

talks with local physicians. The impacts on production approach concept say that an activity's influence on the environment may affect a producer's output, costs, and profitability. If there is a market for goods and services, the value of the change in production, such as the decreased value of fish caught as a consequence of river pollution, may be used to reflect the impacts of environmental impact. EOP has also been used to track the effect of environmental changes on agriculture, forestry, fisheries, electricity, public services, and other sectors, such as soil erosion, deforestation, wetland and reef damage, and air and water pollution [7]. The impact on production approach concept says that an activity's influence on the environment may affect a producer's output, costs, and profitability. If there is a market for goods and services, the value of the change in production, such as the decreased value of fish caught as a consequence of river pollution, may be used to reflect the impacts of environmental impact. EOP has also been used to track the effect of environmental changes on agriculture, forestry, fisheries, electricity, public services, and other sectors, such as soil erosion, deforestation, wetland and reef damage, and air and water pollution. To evaluate the effect, methods such as with and without, as well as before and after, are often employed. The problem with both with and without methods is that we can't observe pollution-affected households without also observing pollution effects. One way to address this issue is to create a control group that is identical to the pollution-affected group except for the pollution. The afflicted groups counter-factual is provided by the control group. However, this is not simple, as finding such a matching group, at least in terms of observable indicators, is difficult. Alternatively, participants in the program may compare before and after circumstances of the same families. This method necessitates the use of baseline data, which is not always accessible. In this case, the second-best solution is reflexive comparison, which compares before and after scenarios for the participating households. This would allow for realistic effect estimations. To begin with, it should be noted that respondents in most of these types of inquiries have a tendency to overestimate the damages. As a result, it's critical to reduce overestimation bias. Every effort was made to reduce, if not eliminate, bias. To some extent, the overestimation problem is addressed by the double difference method, which compares before and after as well as with and without scenarios. Our discussions with local non-governmental organizations (NGOs) and medical professionals have also aided in the cross-checking of damage losses. Figure 1 Shows The Map Showing Study Villages[7].

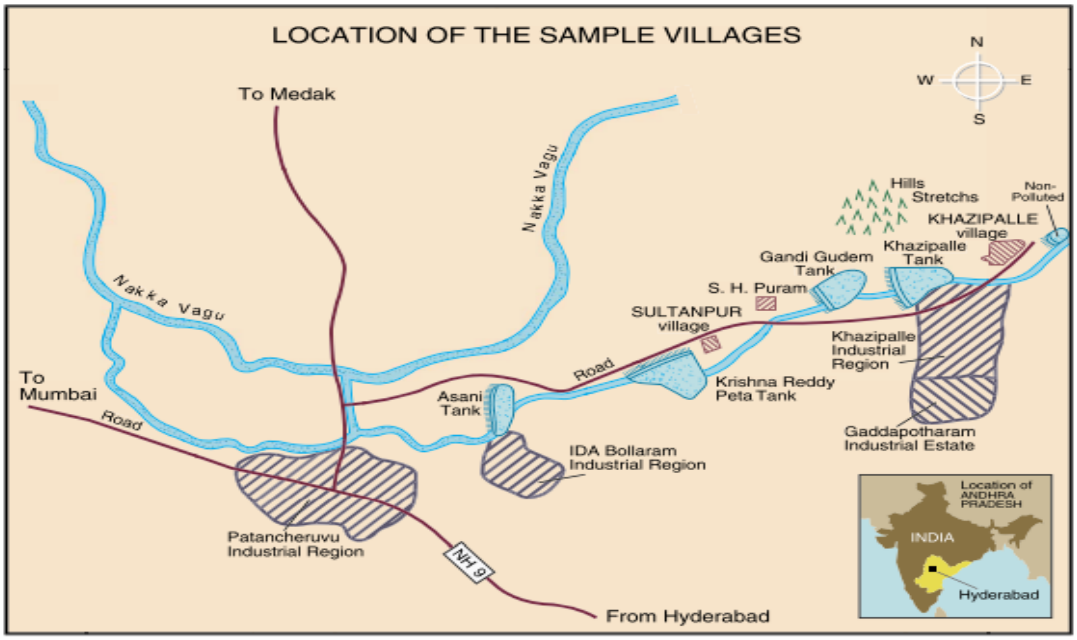

Figure 1: Map Showing Study Villages

2.1.Application:

In rural regions, livestock is often regarded as one of the most important sources of income. All of the local water sources in the contaminated hamlet have been polluted, posing a severe danger to the town's cattle economy. Livestock is forced to rely on contaminated water due to a lack of adequate municipal water sources. As a result of drinking polluted water and grazing on contaminated grasses or grazing areas, livestock have been infected with a variety of illnesses. The locals claimed that during the past five years, 149 livestock perished as a result of drinking contaminated water. Over time, the majority of the cattle get ill. Another major issue in the community is that some cows have lost their ability to reproduce. For their owners, these cows have become a burden. Milk and dung quality has suffered as a consequence of grazing on contaminated grasses and drinking dirty water. People have sold their livestock at extremely cheap prices because they are afraid of further cow fatalities[4].

2.2.Advantages:

To summarize, industrial pollution has a significant monetary effect on rural areas. If social costs such as village alienation (marriages, social visits, etc.) were taken into account, the costs of damage would be much higher. Similarly, determining the true effect on health, both economically and psychologically, is challenging. While there is a risk that respondents will overestimate their damages, we are confident that these excesses would not be greater if social costs were valued. Furthermore, the financial losses incurred by a household's primary breadwinner due to permanent disability are difficult to quantify. In this regard, assessing the problem in terms of pure economic loss valuation is difficult. As a result, the solution to the problem is not to compensate for the loss, but to eliminate the problem entirely. In this case, compensation entails granting the right to pollute. When it comes to the health consequences in this case, no amount of compensation would be enough to solve the problem. Something must be done in addition to compensation to permanently end the problems[8].

2.3.Working:

Apart from lowering agricultural output, contaminated water imposed huge expenses on a variety of agricultural operations, such as corrosion of agricultural equipment, pump set damage, and machine maintenance costs, and so on. Only damage to pump sets has been recorded from Kazipalle village, but other issues such as equipment corrosion and maintenance expenses may have happened earlier. As a result, there has been a decrease in agricultural operations during the past eight years, and they are unable to recall the expenses of repairs or the loss of equipment due to pollution. Pump set damage is still vivid in the thoughts of cultivators since it causes a significant loss to growers. Detergent-laced irrigation water removes lubricants from irrigation oscillates and pumps. Furthermore, an excessive quantity of suspended particles in the water will need regular filter and nozzle cleaning (Pearce et al., 1978). As a consequence, additional expenses such as electric motor maintenance and service, pump set damage, and so on are frequent. These expenses were incurred during the past five years. The annual expenses of repairing and damaging pump sets have been estimated accordingly. The average annual total cost of agricultural operations owing to pollution is Rs. 182 ($3.6) per family per year. Large and medium farmers bear the brunt of the expense of pump set damage. As a result, bore wells are exclusively owned by these farmers. A bore well is not owned by any of the marginal farmers. Large farms have significant per-unit and per-household expenses. Approximately 0.59 hectares per family have become unusable for farming. There is an inverse relationship between farm size and the amount of land that becomes uncultivable, for obvious reasons: big farmers have more land under irrigation per family[9].

3. CONCLUSION

Even though the victims did not agree with the negotiated amount offered by the industries, instead of going to court, the negotiation could have been made more effective and acceptable to all parties by using a realistic estimate of the damages. On the other hand, the majority of families, particularly small and marginal farmers, have benefited indirectly from the industry's job possibilities. Civil society's efforts to improve remuneration for these farmers were ineffective since they account for 90% of the families. Small and marginal farmers lose between Rs. 5000 and 15,000 ($100–300) per family, which is much less than the losses suffered by medium and big farms. Furthermore, since these families are more preoccupied with their day-to-day survival, they are unable to participate in the struggle for justice. Furthermore, their social standing prohibits them from working in the business. The involvement of civic society in this instance is likewise unsatisfactory due to these factors. Both dharma (mass squatting) and rastha rook (road blockage) protests in front of the state Secretariat ended in lathi (cane) charges and arrests of villagers and NGOs. The objections received no response from industry or PCB. People were enraged and began attacking the industries. Since then, companies have ceased dumping their waste into the tank throughout the day. The locals caught the people twice when they were dumping the wastewater into the tank at night and brutally beaten them. After that incident the industries were closed for 3 to 4 days and started again as usual. Despite all these actions, the community did not succeed in influencing either industries or regulatory authorities. The movement could not sustain because a majority of the population have shifted to jobs in the industry leaving agriculture. Thus, the present case study provides an apt example of failure on all fronts, which is mainly due to the nexus between industries, policy makers and politicians coupled with diverse economic interests among the farm households. It is clear that mere passing of laws and creating institutional structures are necessary but not sufficient to address the environmental problems. Policies must be applied in the proper context. Institutions should be strong enough, with more autonomy and powers, to deal with the problems at hand[10].

ABSTRACT

Each country organizes its pension system through taking into account its existing economic, demographic and social problems. At the same time, countries with developed and developing economies, need to reform the pension sector to ensure a decent standard of living after retirement, when they reach a certain level of development. This article examines the pension systems of foreign countries and their peculiarities. Criteria for valorization in the pension systems of foreign countries are given. Based on the experience of foreign countries, proposals have been developed to develop an action plan to improve the management system of mandatory pension payments in Uzbekistan.

KEYWORDS: *Pension Provision, Valorization, Foreign Experience, Compulsory Pension Insurance, Tiered Pension Systems.*

INTRODUCTION

Over the last two decades, there has been a broad understanding of the economic stability of states and the role of pension systems in the social security of the elderly population.

Pension provision is an integral part of social protection of the population of any modern state and one of the main and most important guarantees of sustainable development of society. These guarantees, in turn, are included in the pension system, the purpose of which is to provide financial support to citizens when they reach retirement age or other events in their lives (disability, loss of a breadwinner, etc.).

One of the most important goals of pension reform is to ensure financial stability, that is, to pay pensions now and in the future according to the level of collateral, not to lead to unexpected increases in payments, declining pension payments and lack of pension funds to be liquidated from the state budget.

Strong pension reform should be based on financial forecasts, including short-term and long-term cash flow indicators, and an analysis of the status and expenditure of accumulated funds.

The purpose of this article is to develop proposals and recommendations for the application of best international practices in the pension system of Uzbekistan based on the study of the pension system of developed countries. For this purpose, the article defines the following tasks:

- Analysis of various models of pension systems in developed countries;

- identify problems in the global pension system;

- Disclosure of the specifics of the use of "valorization" in the pension system;

- Development of proposals and recommendations for the use of best international practices in the pension system of our country.

Analysis of the relevant literature.

In the study of the experience of foreign countries, especially developed countries, scientific research can be found in the bases of international scientific research. In addition, Uzbek economists have conducted extensive research on international pension systems.

T. Emelyanova, studying the formation of the pension system, divides it into types according to the following characteristics:

- Subsistence and material security of the disabled;

- Taking into account the share of personal labor of the pensioner in the implementation of pension benefits in accordance with the income of the population;

- Pension provision based on personal initiative.

According to A. Ijaeva, the main factors in the classification of the pension system are:

- On the basis of the method of calculating pension payments and contributions;

- On the basis of functional (distribution and fund) aspects of the pension fund;

- In terms of number and form, firstly - the social pension, secondly, the distribution system, thirdly, the savings system, fourthly, the voluntary savings system.

In his research, D. Rakhmonov noted that one of the important features of the pension system is the division into mandatory and voluntary forms.

In our opinion, there are various pension systems in the world today, the most important of which are two- and three-tier pension systems. The three-tier system includes private pension insurance, state-funded pensions and voluntary (non-state pension system, corporate-funded pension system), while the two-tier system includes private and state pension systems.

RESEARCH METHODOLOGY

The methodology of this article used the methods of analysis and synthesis, scientific abstraction, deduction, classification, generalization, comparative and theoretical interpretation.

In addition, the scientific basis of the article consists of data from international standards and normative documents, research of local and foreign scientists in scientific publications.

ANALYSIS AND RESULTS

World experience in the formation and development of various pension models shows that they are all based to some extent on the principles of compulsory pension insurance (CPI). This situation is explained by the fact that the CPI system is most adapted to the requirements of a market economy and meets the interests of different segments of society.

In many countries, national pension systems based on compulsory pension insurance have the following main features:

a) Pension insurance is mandatory and does not depend on the wishes of the insurer (employer) and the insured person (employee). The state appoints CPI subjects and participants;

b) CPI is funded by insurance premiums and (or) insured persons, in which the state may also participate;

c) Insurance premiums are collected in special funds (cash desks), which assign and pay pensions in the event of an insured event;

d) The amount of insurance premiums and the amount of payments depends mainly on the salary or income of the insured person.

Different models of pension systems are used abroad, including state social security, compulsory social insurance, personal pension insurance, and various other social protection institutions. The pension system of most countries consists of three tiers (Table 1).

The right to receive a state pension is granted to persons of a certain age established in that country. However, in some cases, it is possible to retire earlier or continue working after reaching retirement age.

TABLE-1COUNTRIES WITH A 3-TIER PENSION SYSTEM

Country	First tier	Second tier	Third tier
China	compulsory pension insurance	state pension provision	rural pension insurance
France	basic retirement order	mandatory additional pension provision	voluntary pension funds
Russia	compulsory pension insurance	state pension provision	non-state (voluntary) pension provision
Great Britain	state pension	basic state pension	professional pensionfundsof non-satate pension system
Italy	state and compulsory pension system	private pension insurance	voluntary pension insurance
Germany	private pension insurance	state pension	Production pension

In Germany, for example, although the retirement age is 67 for women and men, it is still possible to retire earlier. To do this, you must pay from personal pension funds the amount specified in the pension legislation (0.3% for each month of non-employment).

In France, every Frenchman, regardless of gender, has the right to retire at the age of 60. However, in order to receive a full pension, he must have 40 years of work experience. French citizens receive a full pension at the age of 65, regardless of length of service. A person who continues to work even after retirement is paid an additional 3% payment for each year of service.

U.S. citizens with 13 years of work experience are eligible for a state pension. In America, the retirement age is 65 for women and 67 for men. However, a person who retires earlier will be paid a pension of 75% of the pension.

In China, the retirement age is 50-55 years for women and 60 years for men. Civil servants who have worked for at least 15 years are eligible for a state pension.

In Japan, the retirement age is 65 years. It is possible to retire earlier, but the monthly pension will be reduced by 25 percent. After reaching the age of 65, the amount of pension is increased by 5 percent annually.

Today, compulsory insurance premiums form the basis of the pension system in many countries around the world. However, in most countries, the payment of mandatory contributions is distributed among employers and workers (Table 2).

TABLE-2 AMOUNT OF MANDATORY PAYMENTS TO PENSION FUNDS (BY COUNTRY, 2019)

Countries	**Allocations to state pension funds (%)**		**Allocations to private pension funds (%)**		**Total**
	Employee	Employer	Employee	Employer	
France	11,2	16,3			27,5
Germany	9,3	9,3			18,6
Italy	9,2	23,8			33,0
Japan	9,15	9,15			18,3
South Korea	4,5	4,5			9,0
USA	6,2	6,2			12,4
Russia		22			22,0

Source: OECD short report "Pensions at a Glance 2019"

Currently, the demographic situation in many developed countries is characterized by a slowdown or even a decline in the growth of the working age population. At the same time, there is a sharp increase in the population over the age of 60 and even over the age of 80, which will inevitably lead to an increase in the number of disabled members of society and the disabled, i.e. retirees.

The main problem is that the "aging" countries of the Western world may not be able to pay pensions to their elderly citizens and provide them with the necessary medical and social assistance. The economic growth rates of these countries are not fast enough.In these countries, the downward trend in the number of workers and, consequently, the number of consumers has become apparent. This process may accelerate in the near future. The population of the developed countries of the world has started to live longer, so their retirement period will also be extended.If the elderly don't want to work until they're 70, and entrepreneurs don't start keeping them employed, economic growth will slow by about a third.

All these factors together have already led to a significant increase in the pension burden on state budgets and have raised the issue of reducing the share of the pension system distributed to governments and increasing the share of the funded pension system. However, the experience of different countries shows that reforming the pension system often leads to social unrest, which is associated with raising the retirement age or waiving preferential pensions, or increasing contributions to pension funds.

The following is an in-depth analysis of the pension systems of developed countries on the example of countries, focusing primarily on the US pension system.

As in many countries, the U.S. pension system is divided into two components: compulsory public insurance and voluntary private insurance. In state insurance, social contributions to the pension fund are paid by the employee in the amount of 7.65% of salary, and the employer pays the same amount. Thus, the total fee is 15.3%.Self-emolyed individuals pay for themselves as both workers and employers - a total of 15.3 percent. Unemployment income, such as interest on

bank deposits and bonds, dividends, and income from securities transactions, is not subject to pension tax.

However, the state pension system is unable to provide Americans with a decent standard of living after retirement, as the wage coverage rate is only 30 percent, while 70-80 percent is sufficient to support a normal lifestyle.To minimize the income gap between working and retired people, there are several voluntary pension systems in the U.S. that allow you to save for future retirement.

In the U.S., the pension system is very flexible, for example, an employee can retire at age 62 that is, before reaching retirement age, and receive an incomplete pension.

The pension system of Germany, one of the most advanced countries in Europe, is the most effective pension insurance system, which is based on the principle of solidarity of generations. According to this principle, payments to the Pension Fund are made by the employed population to support current pensioners.

The pension system in Germany consists of three main levels: compulsory pension insurance, corporate pension insurance and private pension insurance. Categories of the population such as workers, employees, civil servants, home-based workers and farmers are provided with compulsory pension insurance.This pension provision applies not only to qualified and employed persons, but also to a group of people (disabled, widows, students, unemployed, etc.) who for some reason have not entered into a full-time employment relationship in society.Although unable to pay insurance premiums, they are participants in the pension insurance system due to the application of the principle of joint redistribution, which applies within the pension system in Germany.

Unlike compulsory pension insurance for workers and employees in Germany, pension insurance for freelancers (doctors, veterinarians, lawyers, notaries, architects, etc.) has its own characteristics. Freelancers who are self-employed pay higher premiums. Therefore, the amount of their pension benefits is also relatively high.

The second tier of the German pension system is corporate pension insurance. This form of protection of the elderly has a sufficiently clear corporate character and is not considered mandatory. The company independently decides the amount of pension and whether or not to pay pensions, often referred to as “corporate pensions,”.

The third level of social protection in old age is private pension insurance. It provides citizens with the opportunity to receive more social benefits than provided for in the compulsory insurance system, as well as an alternative form of insurance for those who do not participate in compulsory pension insurance. Unlike compulsory pension insurance, the premiums paid to private insurance companies are significantly higher, while the amount of such pensions is also higher.

The three-tier pension insurance system in Germany is mainly based on the principle of distribution of pension benefits and also has some accumulative elements.

Thus, the liability for pension insurance is determined not by the amount of income, if we do not consider low-income people, but by belonging to a particular social group.

The employer pays its share of social security for the employee on a monthly basis. Contributions to the pension system during military or alternative service are paid by the state. In Germany, due to the increase in life expectancy and the decrease in births, the amount of mandatory contributions to the state Pension Fund is constantly increasing, and today it is 20 percent of the employee's salary. In Germany, the retirement age is 67 for women and men. The German government is working hard to raise the retirement age to 70 years.

Another European country, the Italian pension system, represents a three-tier system formed as a result of many reforms implemented over a long period of time.

The first tier of the Italian pension system is compulsory state insurance based on the principle of distribution. The employee allocates a portion of the funds for his or her maintenance after retirement.

Each employee, regardless of their type of activity, is obliged to pay contributions from the income received.

Contributions paid during the period of employment determine the amount of the monthly pension, which depends on the number and amount of payments made by the employee.

There are several types of pensions:

- Old age pension, which is paid when the employee reaches retirement age, in which case the employee must have paid the minimum amount of contributions;

- Old-age pension, which is granted without the condition of reaching a certain age. The employee must work the prescribed length of service, i.e. have the required specific length of service;

- Disability pension is paid to the category of persons who terminate their employment early due to deteriorating health;

- Survivor's pension is paid to family members whose breadwinner has died.

The main reason for the introduction of the second and third stages (additional pension system) is the observation of a decrease in the wage recovery ratio when receiving pension payments from the state pension insurance system, which constitutes the first stage.

Additional pensions in the second tier of the Italian pension system are provided only at the expense of non-state pension funds. Additional pension is a tool that allows you to combine mandatory and additional pensions at retirement. An additional pension is not as the same as mandatory pension.A personal account is opened for each employee, the proceeds of which are then invested in financial instruments (shares, bonds, debt obligations, mutual funds) in the financial market. The profitability of these instruments is determined by the trends in the financial market and the choice of management method.

After the reform, non-state pension funds can be divided into three categories:

- Contractual pension funds;

- Open pension funds;

- Personal pension plans, which in turn are a real insurance policy.

Contractual pension funds established for the benefit of certain categories of workers are considered closed:

- Private workers belonging to the same contract category, the same company or group of companies, the same territory;

- Family members of the employee, if it is provided by the charter of the fund;

- Civil servants belonging to specific areas;

- Members of workers' cooperatives;

- Private entrepreneurs and freelancers engaged in certain activities.

Contractual pension funds established for the benefit of certain categories of workers are considered closed:

- Private workers belonging to the same contract category, the same company or group of companies, the same territory;

- Family members of the employee, if it is provided by the charter of the fund;

- Civil servants belonging to specific areas;

- Members of workers' cooperatives;

- Private entrepreneurs and freelancers engaged in certain activities.

Open pension funds are an additional pension source that can register anyone who intends to receive an additional pension, regardless of employment status. A distinctive feature of open funds from professional funds is the ability to directly manage the funds received at the expense of the fund.

Entities that can form open pension funds include banks, asset management companies, brokerage companies, insurance companies. The fund's assets are not related to the company's assets. In the event of bankruptcy of the company that established the fund, the assets of the open pension fund may not be used to meet the claims of creditors. Even non-working people can become members of an open pension fund.

There are open pension funds that implement individual retirement plans for individuals. Their advantage is the ability to take a break from paying fees and then resume.

The third stage of the Italian pension system is characterized by various forms of asset storage, which is carried out through the use of instruments such as life insurance policies, mutual investment funds, postal certificates of deposit, bonds.

Currently, an Italian citizen can become a full-fledged pensioner at the age of 66. This is the same retirement age for men and women. A few years ago, the age limit was a few months lower. The increase in the retirement age is associated with the rapid aging of the population.

According to the World Health Organization, average life expectancy in Germany is 83.1 years, in Italy - 82.7 years, in the United States - 79.3 years, in Russia - 70.5 years. Thus, German retirees receive an average of 16 years, Italians - 16 years, Americans - 12 years, Russians - about 10 years.

In the world practice, the "valorization" indicator is widely used in the pension system. Valorization is the adjustment of the amount of previous income in accordance with the changes in living standards that occurred in the period between the start of work experience and retirement savings. It is clear that there is no need to valorize the pension when using the schemes of calculation of the final salary. Valorization has become a permanent practice in long-term pension payment schemes.

Until recently, although valorization had a significant impact on pension payments, it received less attention than an indexation policy similar to valorization in the payment of pensions.

TABLE-3INCOME LEVEL AND VALORIZATION: SCHEMES FOR CALCULATING PENSIONS BY INCOME LEVEL

Countries	**Income, the duration of its measurement**	**Valorization**
United Kingdom	The average level of income over the total period of employment	By average income level
Germany	The average level of income over	In terms of the average income

	the total period of employment	level, it is adjusted according to the change in the level of deductions for the selected pensions
Italy	Average income level for the whole period (nominal values)	Transition to a system of calculations based on the level of GDP growth once in 5 years
United States	35 years with the highest income	On the average income level for individuals under the age of 60, on the price level for individuals aged 62 to 67 years
France	20 years with the highest salary, transition to 25 years (for state schemes)	By price level (for state and professional schemes)
Japan	Average level of income in employment (occupational pension)	By average income level

The table shows that adjustments related to valorization in income-based pension systems are made in different ways. A direct result of valorization in conditional-savings account systems is the application of a conditional interest rate, which also serves to adjust pension payments between the time they are accumulated and the time they are paid. In point-based systems, the procedure for revaluing a retirement score leads to the same result. The last column of Table 3 shows the rules of valorization, as well as the rules of the relevant conditional-savings accounts and points system.

CONCLUSION

There is a high need to improve the management system of compulsory pension insurance based on the experience of foreign countries to increase the efficiency of management of the system of compulsory pension insurance in the Republic of Uzbekistan. To do this, it is necessary to develop measures aimed at:

a) Implementation of the principle of tripartism in decision-making on the development of pension legislation and optimization of the mechanism of interaction of social partners;

b) Conducting the activities of compulsory pension insurance and other types of compulsory social insurance on the basis of common principles using a common database;

c) Harmonization of compulsory pension insurance with other types of compulsory social insurance;

g) Formation of a single actuarial evaluation system, including standardization of actuarial activities;

d) Improving the legislation governing the activities and legal status of the Pension Fund of the Republic of Uzbekistan.

In addition, in order to increase the targeted provision of social guarantees and legalize the hidden labor market, it is necessary to improve the system of personalized registration of citizens in the field of compulsory pension insurance, electronic record keeping of labor and social documents of citizens.State pensions are the main source of livelihood for certain segments of the population. For another category of socially vulnerable citizens, they are the non-core but significant income of the family budget. Therefore, the pension system in the country must always be stable and strong. In conclusion, state pensions in the country are regulated by

constantly updated and improved legal norms.The pension system works stably and rationally. However, in order to increase the efficiency of retirement activities, it is necessary to make some changes to the regulatory framework, which will lead to significant positive changes.

Thus, the pension reform in Uzbekistan is based on global development trends in this area through taking into account foreign experience, especially the experience of foreign countries such as the United States, Germany and Italy.An important element of pension reform in this group of countries is the increase in the amount of pension savings. It is the accumulative part that is a means of eliminating the dependence of the pension system on demographic trends and increasing the overall level of pension payments.An analysis of the key elements of pension reform in Germany, Italy and Russia suggests that the new Uzbek pension system is not the same as in European countries, but has some commonalities. In developing a new pension model, Uzbekistan should undoubtedly rely on new foreign pension schemes, but at the same time keep in mind that pensioners have their own characteristics, which are determined by factors such as income, national financial market development and inflation.

As the world experience shows, there are two ways to solve the financial problems of pension systems:

1) To maintain the state distribution pension system, albeit in a slightly reformed form, and at the same time to encourage the development of additional voluntary private pension programs;

2) Introduction of a new multi-level distribution-funded pension system financed from various sources.

In short, the development of pension systems in foreign countries is associated with many areas of society, such as the development of the economy, social sphere, and insurance culture of the population, financial institutions and the peculiarities of the demographic situation.It is necessary to rely on the study of international experience in the development and implementation of measures to improve pension systems, the use of science-based approaches to assess the prospects for the development of compulsory and voluntary pension insurance.

ABSTRACT

The article presents the results of studies on the solubility of the phosphoric acid-hexamethylenetetramine-water system. The formation of new chemical compounds was established, which were identified by methods of physicochemical analysis. In addition, the results of a study on thermal analysis of 2 $(CH_2)_6N_4 \cdot H_3PO_4 \cdot 2H_2O$ at various temperatures are presented.

KEYWORDS: *Phosphoric Acid, Hexamethylenetetramine, Solubility, PolythermOf The System, Liquid Phase, System.*

INTRODUCTION

One of the key tasks facing fundamental and applied science is to solve problems and take a non-standard approach to improving the reliability of equipment operation and protecting materials from aggressive influences in oil and gas production and processing enterprises [1].

There are several ways to determine the rate of corrosion in various environments [2]. Of these, modern and not inferior in accuracy in determining the rate of corrosion by the classical method, a method using the measurement of polarization resistance. Based on the experimental data, graphical dependences of the change in the polarization resistance of the electrodes over time were plotted, and the corrosion rates were calculated depending on the thickness of the coatings.

In order to characterize the interaction of components in an aqueous medium and to obtain

materials for an anticorrosive coating based on phosphoric acid, hexamethylenetetramine, the solubility in the H_3PO_4 - $(CH_2)_6N_4$-H_2O system was studied by the visual polythermal method [3].

Heterogeneous equilibrium in the H_3PO_4 - $(CH_2)_6N_4$ - H_2O system was studied by five internal sections in a wide concentration and temperature range. Based on the results obtained, a polythermal diagram of the solubility of this system was constructed: from the eutectic freezing point

(-86,8^{0}C) up to 70,0^{0}C. The liquidus surface of the solubility diagram of the H_3PO_4 - $(CH_2)_6N_4$-H_2O system consists of eight crystallization fields of solid phases: LED, $2H_3PO_4 \cdot H_2O$, $(CH_2)_6N_4 \cdot H_2O$, $(CH_2)_6N_4$, $2(CH2)_6N_4 \cdot H_3PO_4$, $(CH_2)_6N_4 \cdot H_3PO_4$, $(CH_2)_6N_4 \cdot H_3PO_4\, 2H_2O$, $(CH_2)_6N_4 \cdot H_3PO_4 \cdot 4H_2O$ (Figure 1).

The fields converge at eight triple invariant points of coexistence of three different solid phases (Table 1). The polythermal diagram shows the solubility isotherms every 100^{0}C.

In the studied system, compounds of the following compositions are formed as new phases: $2(CH_2)_6N_4 \cdot H_3PO_4$, $(CH_2)_6N_4 \cdot H_3PO_4$, $(CH_2)_6N_4 \cdot H_3PO_4\, 2H_2O$, $(CH_2)_6N_4 \cdot H_3PO_4 \cdot 4H_2O$.

The crystallization fields of the compound $(CH_2)_6N_4 \cdot H_3PO_4$ occupy the main part of the polythermal diagram, which indicates its low solubility in comparison with other components of the system. The system has three double and eight triple nodal points and equilibrium solution compositions.

According to the solubility diagram, as a result of the interaction of phosphoric acid with hexamethylenetetramine in the H_3PO_4 - $(CH_2)_6N_4$ - H_2O system, hydrated compounds are formed with a phosphoric acid: hexamethylenetetramine molar ratio of 1: 1 and 1: 2. It was found that hydrated compounds with a molar ratio of the starting components of 1: 1 exist under relatively low temperature conditions. Above 28 ^{0}C they do not exist in the system.

The formation of the compound with the ratio H_3PO_4 :$(CH_2)_6N_4$ 1: 2 occurs in the region of the system richer in hexamethylenetetramine. The minimum concentration of phosphoric acid that causes the formation of this compound - 8,8%.

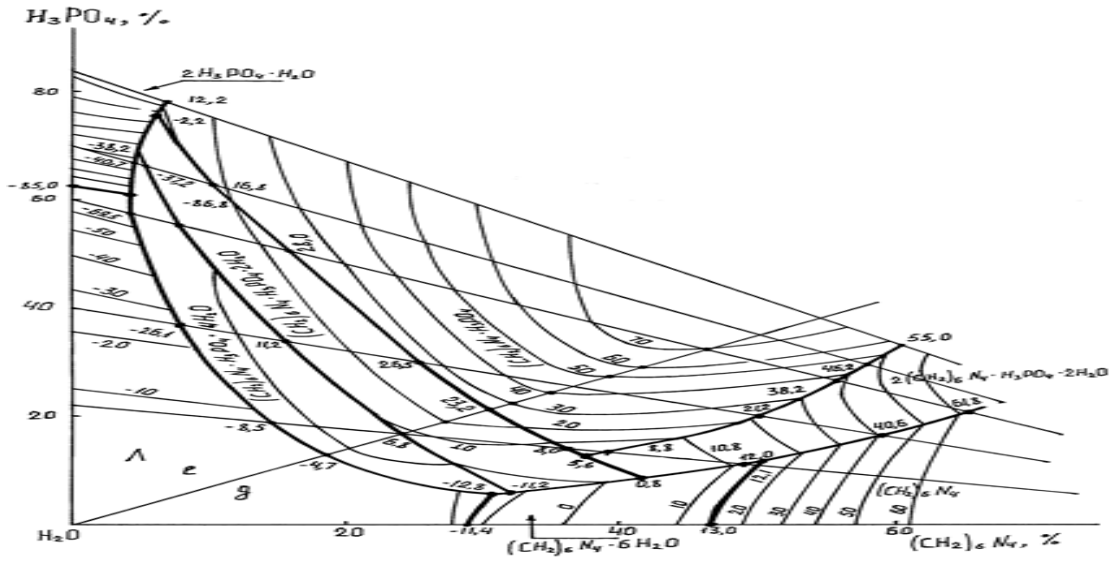

Fig. 1. Polythermal diagram of the solubility of the phosphoric acid-hexamethyleneteramine-water system.

TABLE 1 DOUBLE AND TRIPLE POINTS OF THE SYSTEM PHOSPHORIC ACID - HEXAMETHYLENETETRAMINE - WATER

Liquid phase composition, %			Tem-ra kr, ^{0}C	Solid phase

The compounds found in the studied system were isolated in the crystalline state from the assumed region of their crystallization and identified by chemical, X-ray phase, IR spectroscopic and thermogravimetric methods of physicochemical analysis.

From the results of the chemical analysis shown in Table 2, it can be seen that the content of phosphoric acid, hexamethylenetetramine and water in the obtained compounds is in good agreement with the composition described for them.

TABLE 2 CHEMICAL COMPOSITION OF THE ISOLATED COMPOUNDS OF HEXAMETHYLENETETRAMINE WITH PHOSPHORIC ACID

Compound	**Found, %**			**Calculated, %**		
	H_3PO_4	$(CH_2)_6N_4$	H_2O	H_3PO_4	$(CH_2)_6N_4$	H_2O
$H_3PO_4 \cdot (CH_2)_6N_4 \cdot 4H_2O$	31,56	45,22	23,22	31,61	45,16	23,23
$H_3PO_4 \cdot (CH_2)_6N_4 \cdot 2H_2O$	35,80	51,05	13,15	35,77	51,09	13,14

$H_3PO_4 \cdot (CH_2)_6N_4$	41,23	58,77	-	41,18	58,82	-
$H_3PO_4 \cdot 2(CH_2)_6N_4$	23,71	67,86	8,43	23,67	67,63	8,70

Comparison of interplanar distances and relative intensities of diffractoliniums of hexamethylenetetramine and its hydrated compounds with phosphoric acid show that the new compounds differ from those for the initial component. Compounds $(CH_2)_6N_4 \bullet H_3PO_4 \bullet 2H_2O$ and $2(CH_2)_6N_4 \bullet H_3PO_4 \bullet 2H_2O$ have an individual crystal lattice (Table 3) [4].

TABLE 3 INTERPLANAR DISTANCES AND RELATIVE INTENSITIES ON X-RAY DIFFRACTION PATTERNS OF HEXAMETHYLENETETRAMINE AND ITS COMPOUND WITH PHOSPHORIC ACID

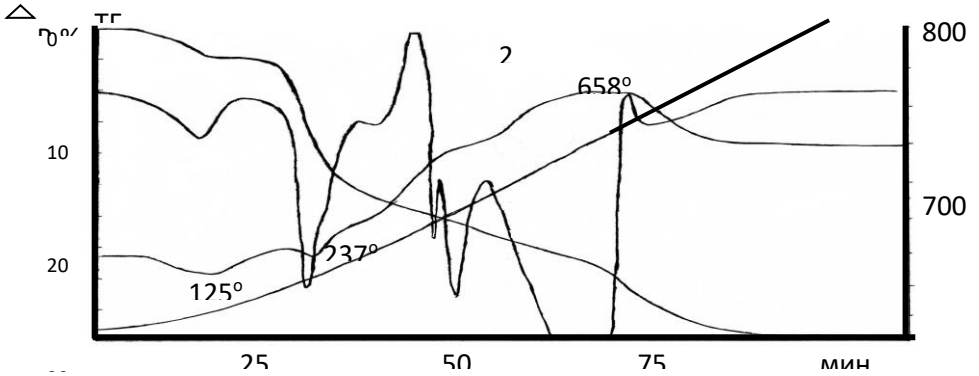
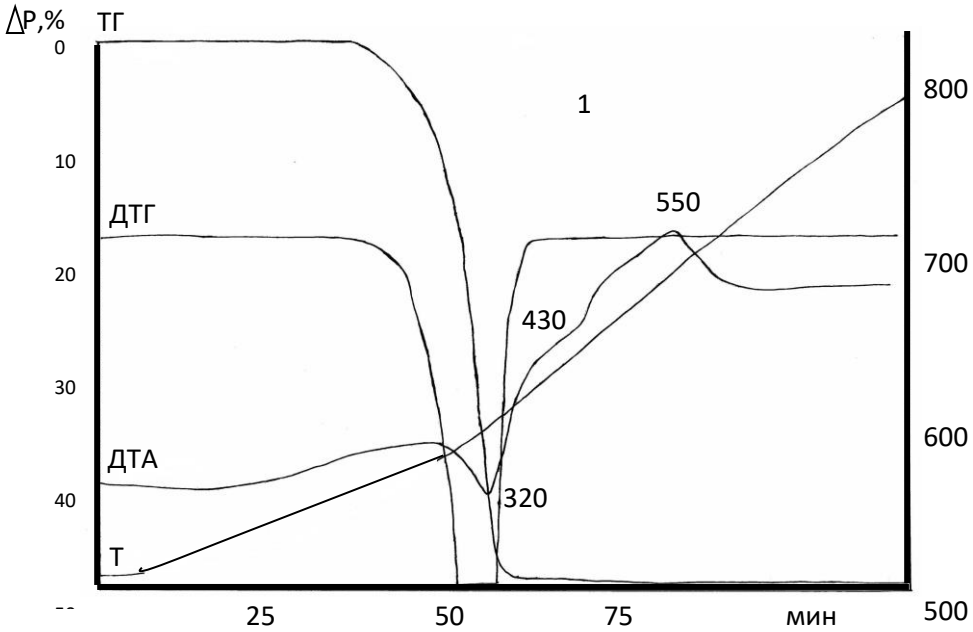
	4,468	100,0	2,405	27,0	1,707	6,0
	3,759	31,5	2,280	16,0	1,617	5,0
	3,469	20,0	2,180	18,5	1,593	5,5
	3,255	92,0	2,170	33,5		

The heating curve of the hexamethylenetetramine sample shows endo-effects at 170^0C; 320^0C and exo effects at 430^0C; 550^0C (Figure 2).

The nature of the first endo-effect is due to the onset of decomposition of hexamethylenetetramine. Weight loss in the temperature range 150-250^{0}C according to the TG curve is 8,42%. A further increase in temperature leads to intensive decomposition of the product. In the temperature range 250-390^{0}C, the weight loss is 89,47%. The nature of the subsequent exothermic effects is due to the combustion of thermolysis products. Total weight loss along the curve TG is 99,47%.

The DTA curve (Figure 2) of the compound $(CH_2)_6N_4 \cdot H_3PO_4 \cdot 2H_2O$ is somewhat different from that of hexamethylenetetramine. The DTA curve shows two endothermic effects at 125 and 237^{0}C and two exothermic effects at 420 and 658^{0}C. The endothermic effect at 125^{0}C is accompanied by a weight loss of 13%. A further increase in temperature leads to intensive decomposition of the product. In the temperature range 175-295^{0}C, the weight loss is 34,36%.





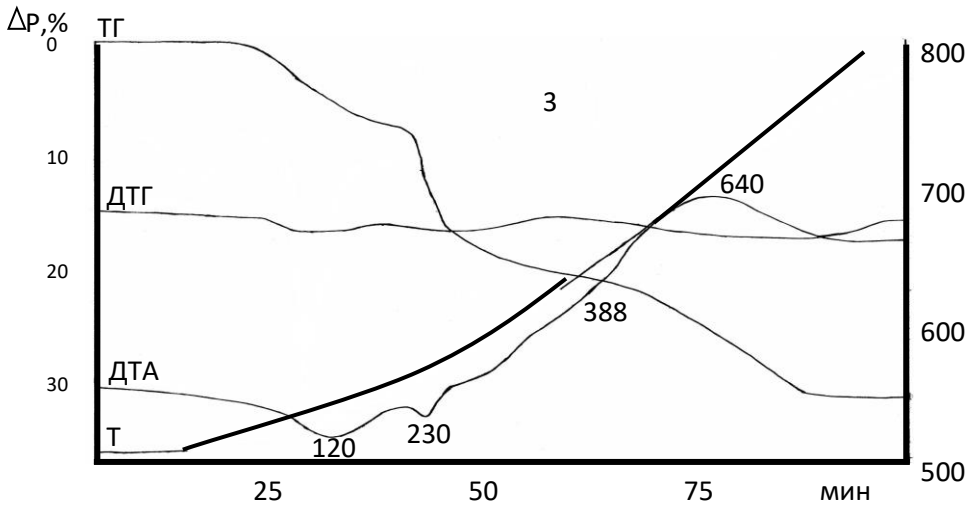


Fig. 2. Derivatograms $(CH_2)_6N_4$ (1), $(CH_2)_6N_4 \cdot H_3PO_4 \cdot 2H_2O$ (2) и $2(CH_2)_6N_4 \cdot H_3PO_4 \cdot 2H_2O$ (3)

It is shown that a further increase in temperature leads to the destruction of thermolysis products. The last two exothermic effects occur with the combustion of the remaining product. The total weight loss at 700^0C, according to the TG curve, is 38% [5].

Thus, the heating curve 2 $(CH_2)_6N_4 \cdot H_3PO_4 \cdot 2H_2O$ is characterized by endothermic effects at 120^0C; 230^0C and two exothermic effects at 388^0C - 638^0C. The first endothermic effect occurring in the temperature range 90^0C-120^0C corresponds to the removal of crystallization water. At the same time, the weight loss is 8,43%. The second endothermic effect occurs in the range 130^0C-230^0C. The weight loss is 10%. The nature of the endothermic effect is due to the intensive decomposition of the product. Weight loss in the range 200^0C-310^0C is 37,35%. Further heating leads to decomposition and combustion of decomposition products. The total weight loss is 97,23%. This is because the thermal behavior of hexamethylenetetramine and its compound with phosphoric acid differ from each other.

Thus, based on the data obtained and the study of the solubility of the phosphoric acid-hexamethylenetetramine system (aqueous solution), it should be noted that the new compound formed makes it possible to obtain and further use anti-corrosion coatings on metal structures with manifestations of rust.

ABSTRACT

Virtual reality teaching and learning applications have been a focus of academic study for decades. There have been big developments over the last five years and technology for virtual truth is moving closer to education. This document provides an overview of the use of virtual reality in education on the Oculus Rift network, in particular. This article examines the uses of virtual reality in education, with an emphasis on the Oculus Rift platform. The goal of this study is to see how virtual reality may be utilized in education and learning. This study's results show how information is provided in virtual reality apps and which the best educational virtual reality applications for users are. This research aims at investigating the recent use of virtual reality in education and learning. The results of this study demonstrate how the curriculum material is distributed in applications of virtual reality and what the best applications of education in virtual reality are.

KEYWORDS: *Application, Augmented Reality, Construction, Input, Virtual Reality.*

1. INTRODUCTION

Virtual reality (VR) is a virtual experience that may be both comparable and dissimilar to the actual world. Virtual reality has a variety of uses, including entertainment (such as video games), education (such as medical or military training), and business (e.g. virtual meetings). Augmented reality and mixed reality, often known as extended reality or XR, are two more kinds of VR-style technologies. There are two kinds of virtual reality: immersive VR and text-based networked VR (also known as "Cyberspace").When you move your head, the immersive VR alters your perspective. While both VRs are suitable for teaching, distant learning is best done in cyberspace. In certain instances, these two kinds are even mutually beneficial. This article focuses mostly on immersive VR. Figure 1 shows the virtual reality[1].

Figure 1: The above figure shows about the Virtual reality [learn].

Currently, typical virtual reality systems produce realistic pictures, sounds, and other sensations that mimic a user's physical presence in a virtual world using virtual reality headsets or multi-projected environments. A person using virtual reality gear may gaze around the virtual environment, move about in it, and interact with virtual features or objects. VR headsets with a tiny screen in front of the eyes are frequently used to get this effect, but it may also be achieved in specially built rooms with numerous big displays. Virtual reality usually includes audio and visual feedback, but haptic technology may also enable additional kinds of sensory and physical input[2].

For a long time, virtual reality teaching and learning applications have been a focus of academic research. Significant progress has been achieved in the last five years, and virtual reality technology is becoming more integrated into education. This article provides an overview of virtual reality's applications in education, focusing on the Oculus Rift platform. The purpose of this research is to look at how virtual reality may be used in learning and teaching. The findings of this study explain how content is delivered in applications of virtual reality and which the best educational virtual reality applications for users are [3]. While VR has come to the attention of the public since the 1980s, the VR headsets have seen so much sales growth over the last decade. New hardware is now available on the consumer market, which provides competitive price models but also fully develops and develops new technology. The roots of modern virtual reality can be traced back to 2012 when an Oculus Rift Kickstarter project was launched in order to bring a high-quality cost-effective head-mounted (HMD) display to the public. The Oculus Rift's preproduction process included multiple models that gave developers the opportunity to build applications before official launch. The new edition of Oculus Rift S is fitted with an LCD monitor with a resolution of 2560 per 1440[4].

This analysis offers a timely overviews of the present state of research on the virtual and increased reality of tourism via its mapping of what is understood[5]. The following aims have been achieved in the systematic quantitative literary study of papers published in tourism and hospitality journals. First is for identifying the sectors and contexts of tourism that have emerged from VR and AR research, second is for identifying types of VR and AR that have received the maximum attention in tourism research, third one is a summary of the emerging opportunities

and challenges of tourism change for R&D is taken from the results of the study. With the growing emphasis on VR technologies, a range of detailed overviews of VR applications for education and systematic mappings already exist (Jensen and Konradsen). Merchant and others for example, concentrate on VR desktops in education, whereas Jensen and Konrad Sen stress the use of HMD technologies. Jensen and Konradsen have a common emphasis in learning and performance; these aren't unique to their target audience which includes higher education, job training, vocational training or K12. In addition, these two studies does not discuss basic theories for the creation of VR applications and the elements used in designing of VR applications. Figure 2 shows the flow of review process.

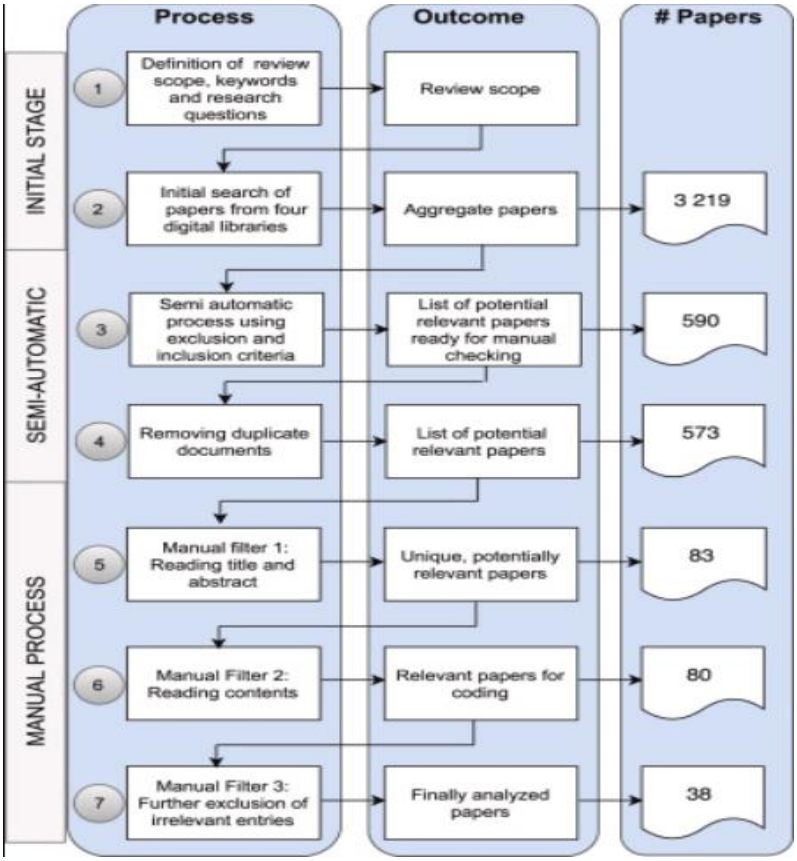

Figure 2:The above figure shows the flow of review process.

The growing reality is a technology more recent than the VR and demonstrates an interdisciplinary system of implementation, in which education and education now tend to be the most research area[6]. In reality, AR promotes learning, e.g. improving material comprehension and maintaining memory and encouraging learning. However if VR takes advantage of simpler and more detailed application and analysis areas, AR continues to evolve in scientific scenarios[7].

1.1 Virtual Reality Hardware:

A variety of devices is utilised to give consumers with an immersive, high-fidelity VR experience. Given the significance of sight in our interactions with the environment, we propose combining a display system that displays pictures in such a manner that the user believes them to be 3D (as opposed to viewing a 2D projection of a 3D scene on a conventional TV or computer screening). combined with a head tracking system considered as the least possiblerequirements sets for experiencing a highly immersive VR experience[8]. Almost all VR applications used this sort of hardware. Additional characteristics include input from movement capture, input from 3D control systems, haptic feedback, input from voice control, olfactory, burning, facial

recognition, audio and/or audio recording. The peripheral capabilities lists these features. Consider a VR experience designed for testingeasiness of a product assembly to help you recognize how peripheral and core capabilities are used collectively to construct more convincing experience[9]. The monitoring of a VR experience from different angles could include only core VR capacities. However if the experience is combined with haptic feedback and 3D input devices, it becomes interactive, and the user may try to build the product in virtual reality during interference and collisions. In comparison, it would probably be hard to change this particular experience to add an olfactory display to create virtual smell.

1.1.1 Display:

The display generally is at the heart of VR experience and is first option when any VR application is built. VR displays vary from regular displays, since a different image can be viewed in each eye. This capability to view individual images in every eye allow slightly offset images to be reflected in each eye sameas the physical world. The consumer gets the idea of seeing a real 3D scene when the virtual world is viewed as such. Although technology has been in place since at least the 1960s, historically, the experience has been prohibitively costly, unmanageable or of poor quality. VR displays typically fall into a single group: CAVE or head mounted displays Automatic virtual experience (HMDs).

1.1.2 Cave Automatic Virtual Experience:

It appears that CAVE technology was first researched at Illinois University's Electronic Visualization Lab. For its entire construction, the CAVE comprises of a space where all 4 walls, ceiling and floor consist of projection screens, a special set of glazing synchronized to the stereoscopic images projectors and a device used to feel and report the site and the viewers' eyes, as well as a computer trained in the measurement and display of the scenes and the projectionists. CAVE technology was first shown to be superior to other usable stereoscopic displays in most respects. These statements included greater field of view (FOV), enhanced visual acuity and improved collaboration support. Although many of these statements have been valid at the time, HMDs approach and compete with CAVE technology capabilities.

1.1.3 Exclusion and inclusion method:

The use of KH Coder 3 was intended to extract articles' collections into word clusters rather than to carry out full machine linguistic content analysis. The tool offers Term Extract, which automates the extraction of word clusters, which often take place with one another – for example, 'virtual space navigation.' The same term could occur, or accidental, clustering in two clusters, like "virtual space" and "navigation.' Each word cluster was therefore entered and the highest scoring clusters were therefore considered to be reliable[10]. This method varies completely from simply extracting a frequency word list in which every extracted word is listed depending on its occurrence frequency. In the procedure, a list of word clusters has beenreturnedwith scores and have selected manually the 1,000 most significant words and clusters which were obtained as a result of this process. This led to a reduced collection, during the subsequent manual process, of potentially relevant objects, which must be classified as "relevant" and not relevant."

1.2 Virtual Reality's Advantages:

1.2.1 Assists with Impressive Visualization:

Virtual reality's brilliance is undeniable. It aids in the discovery of different information and may even change the degree of difficulty. You may get the highest quality visuals if you use a VR headset. Allows Students to Engage — Conducting classroom interaction sessions has grown challenging for instructors in recent years. Interaction with students has been much easier with

the advent of Virtual Reality technology. The pupils to talk about their own experiences use virtual reality.

1.2.2 Creating Interest:

Virtual Reality has made watching rather than reading more pleasurable. The technological aspects of virtual reality are fascinating and intriguing. Virtual reality technology provides pleasurable experiences. This technology encourages kids to study more and get a better understanding of life.

1.2.3 Increases Educational Value:

Doctors use virtual reality technology to learn about new medical characteristics. Virtual reality also excels in the areas of editing and content creation. It aids in the detection of content errors. Some software configurations are recommended for defect detection. VR technology also aids in the creation of ideal editing choices.

1.2.4 Assistsin the Overcoming of Language Barriers:

Language barriers are a major issue in education. If you are not studying in your hometown, you must learn the local dialect of the location you are contemplating. The employment of appropriate software in conjunction with the installation of Virtual Reality allows for the proper implementation of any conceivable language.

1.3 Virtual Reality's Drawbacks:

1.3.1 Lacks Flexibility:

You can be more flexible in the classroom. You are willing to provide recommendations and ask questions. Virtual reality makes this impossible. You may use the same application in all of your sessions with the virtual reality headset. Positive interaction is not possible.

1.3.2 IneffectiveHuman Interactions:

Virtual Reality has a number of drawbacks. The traditional educational system is mostly focused on interpersonal relationships and individual human communication levels. Virtual Reality is an entirely new idea. It is just you and the program here.

1.3.3 BecomingAddicted:

Virtual Reality addiction is very prevalent. The virtual environment has the potential to become addictive to pupils. A segment of the population is becoming hooked to video games and other forms of entertainment. One may even get addicted to dangerous substances in the virtual reality environment.

2. DISCUSSION

A variety of studies have been carried out in education and training on the uses and usefulness of virtual reality. McLellan presents a comprehensive overview of literature related to the study and use for education and training of virtual reality. Ducan, Miller and Jiang identified the benefits of virtual environments as a la for collaborative work, entertainment and socialization in teaching and learning. However it was stressed that it should not be in the interests of any social, minority or disability groups that virtual worlds are used for learning. The digital library of Scopus has published between 59 peer-reviewed articles in the study titles “virtual reality” and “systematic review,” which relate to education, training, teaching or learning, in our research into current systematic reviews and VR mapping studies in an educational context. Neuroscience (11 percent), social sciences (15 percent), psychology and Medicine (78 percent) were the most common fields covered by these systems assessments (11 percent). By analyzing the abstracts of the reports, we further filtered the search results for the element of the immersion. 18 papers, of

which four were highly important, were listed and the findings of a systematic mapping analysis were presented. Furthermore, we found two other related posts, one describing a summary and one describing a Meta analysis. Therefore, we discuss six review articles altogether and present them briefly to highlight our structural mapping study's research void. Increased student interest and enthusiasm for learning were motivated by the incorporation of virtual reality into the curriculum[5] have created virtual reality software, in which students work together to 710visualize a transformer which is installed in a substation and operation and maintaining of virtual environment.

Gilbert identified the popular abstraction of science topics by students that require a deep understanding and ability to visualize. Visualization technology, such as virtual reality, can help students better comprehend the issue of misunderstanding. Virtual worlds are described as permanent, 24/7-open virtual environments that allow avatar representatives to develop, play and interact in real time (representation in 3D form). There was a mistake. Second Life is an online virtual world where avatars may socialize, communicate, and create their personal virtual places. Huang et al.in present timeis one among the most active virtual world sites. Second Life has 36 million residents and over one million monthly active users (Linden Lab). In ten years, transactions in the virtual global economy totaled USD 3.2 billion. In addition to virtual worlds like STA, Hyatt,Starwood and Crowne, the increasing success of virtual worlds hasn't been overlooked in tourism with Serbia, Maldives, Kazakhstan, Estonia, Sweden and Italy.

3. CONCLUSION

Virtual reality presents the education industry with both challenges and opportunities. The advantages of VR technologies are completely controllable, functional and safe as education and training tools. With the advancement of 3D simulation technology, a growing variety of teaching and education materials can be used in the world of virtual reality. Theresearch offers asummary of applications of VR on the Oculus Rift Platform for education and training. The results of the research show that medicine, space, history and nature dominate the delivery of curriculum material in virtual reality applications. More than 50% of applications are freely available without any cost in the majority of apps using English as a communication language.

For each educational application, we gathered information on the average user's star rating and the no. of reviews. Based on user ratings, we computed a Bayesian average from the data and ranked the top 10 educational virtual reality applications. Some studies show that the use of IVR systems in healthcare is still limitable in simulation disease. This is a continuous field of research in the IVR community, and potential changes to IVR's device architecture are likely to enhance IVR technology's usability with the general population. In the meantime, this study stresses the need to establish and enforce best practice recommendations for system IVR. In addition, IVR systems do not accommodate all demographics – a significant concern for health applications. IVR technology may however be customized to the needs of particular groups including people with blind or low vision. The development of an IVR-specific professional contracting company is a positive move in this direction. To this end, the technical and clinical team members need to be closely aligned to optimize the effectiveness of any new or proposed method.

THE BRIEF REVIEW ON THE HARMONICS IN ELECTRICAL CIRCUIT

Mr. Manoj Kumar Ojha*

*SOEIT, Sanskriti University, Mathura,
Uttar Pradesh, INDIA
Email id: manoj@sanskriti.edu.in

ABSTRACT

As every industry becomes increasingly internationalized, the quality of energy has been changing year after year. Because technology is now going towards digital, electrical equipment is in lesser demand than digital equipment. Engineers, on the other hand, are attracted to electrical disturbances or harmonics. Harmonics may reduce or affect electrical network efficiency; therefore power engineers are concerned with harmonics and harmonic reduction methods. The use of power electronics, which is also responsible for harmonic production, has increased the number of power system applications in daily life. There are two kinds of loads in an electrical circuit: nonlinear and linear. Nonlinear loads cause zero sequence current, also known as harmonics current, which is produced in the neutral conductor and may disturb the circuit's waveform by affecting the voltage and current levels. Harmonics are a serious problem that may be solved by using the right filters and voltage current ratings. Many components of the electrical network use filters, such as LC filters, to neutralize zero sequence harmonics and certain other harmonics present in the system, increasing power factor rating. Harmonic distortion is discussed in this article, as well as techniques for minimizing it.

KEYWORDS: *Power System, Power Electronics, Harmonics, Filter, LC Filter, Power, Voltage, Current, Linear and Nonlinear Load.*

1. INTRODUCTION

Harmonics in power systems, especially in AC, are mostly produced by a fast increase in non-linear loads, which is caused by specific devices, such as variable frequency drives, that change their value when a circuit disruption occurs [1]. This is due to advances in technology, such as the use of power electronics circuits and gadgets. The usage of digital technology, as everything becomes digital, causes these harmonics problems [2]. Electronics such as microprocessors, microcontrollers, and arduino are accountable for generating output fluctuation due to the highly sensitive nature of nature. A power system containing power electronics components regulates AC/DC transmission links or loads, whether heavy or light, resulting in overall harmonics in the

system. Figure 1 depicts the different kinds of active power filters. Harmonics are classified into three groups.

- Control device
- Domestic load
- Industrial load

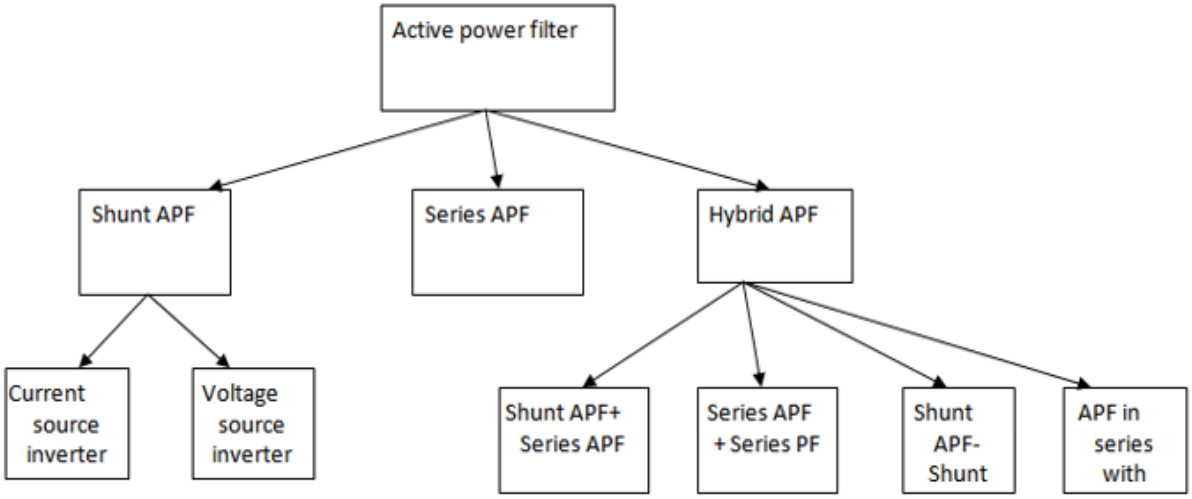

Figure 1: The Various Types of Filter for the Active Power.

Harmonics cases due to non linear load and non linear load is produced due to none obeying the ohm's law, when harmonics current or voltage it has distorted waveform so a compensator used to minimize or normalize the effect of non sinusoidal wave on it. A compensator can be comes in use only when all the component of the electrical circuit able to work accurately and have connection between the loads.

1.1.Measurement of Harmonics:

Measurement of harmonics of a circuit is by harmonics analyzer or digital storage oscilloscope. Oscilloscope is of two types analog and digital so it is used to measure the amount of distortion in the sinusoidal wave. Each harmonic frequency (f_n) is given by the equation $f_n = n \bullet f_1$ where n is the harmonic number and f_1 is the frequency of the first harmonic[3].

1.2.Effects of Harmonics:

Harmonics can affect any electrical and electronics device because sudden rise in current may lead to heating problems and low voltage can cause speed problems in the device also increase in voltage leads to the insulation failure[4].

Effect of harmonics on transformer also transformer is a static device used to convert voltage from lower to higher or from higher to lower named as step up transformer and step down transformer, transformer is a nonlinear device means it does change its resistive value when voltage starts fluctuating[5]. Major effect of the harmonics on the transformer is the heat losses, and that heat loss is additional loss caused by the harmonics current[6].

Some more problems associated in transformers due to harmonics like resonance between transformer inductance and system insulation, capacitance, mechanical insulation and stresses

due to core of transformer (iron core) vibration and temperature rise[7]. In transformers various types of losses present in which heat loss, iron loss, copper loss, hysteresis loss and humming loss present, these losses can induce due to harmonics, means due to harmonics eddy current loss in the transformer increases due to which efficiency of the transformer decreases[8].

Harmonics for any circuit is the amount of unwanted rise in frequency wave which is superimposed on the input wave and distort it which causes many equipment failure and losses in the electrical circuit. Harmonics can be find out by n*f where f is the fundamental frequency of India (50Hz)[9].Figure2 shows the Harmonics waveform having fundamental. 5th, 6th, 7th and total harmonic.

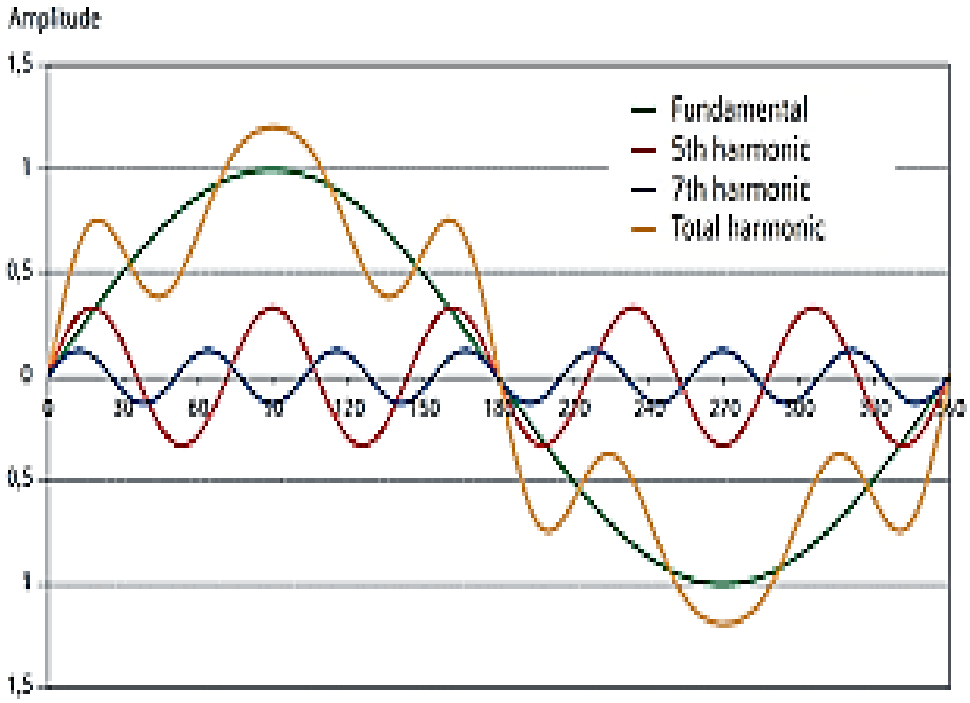

Figure2: The Harmonics Waveform Having Fundamental. 5th, 6th .7th And Total Harmonic

Every equipment is sufficient for producing a signal that will produce even/ODD harmonics some of the equipment produced either ODD or EVEN harmonics.Figure 3 shows the harmonics formation for the 5th, 6th .7th and total harmonic having fundamental sine wave and square wave component.

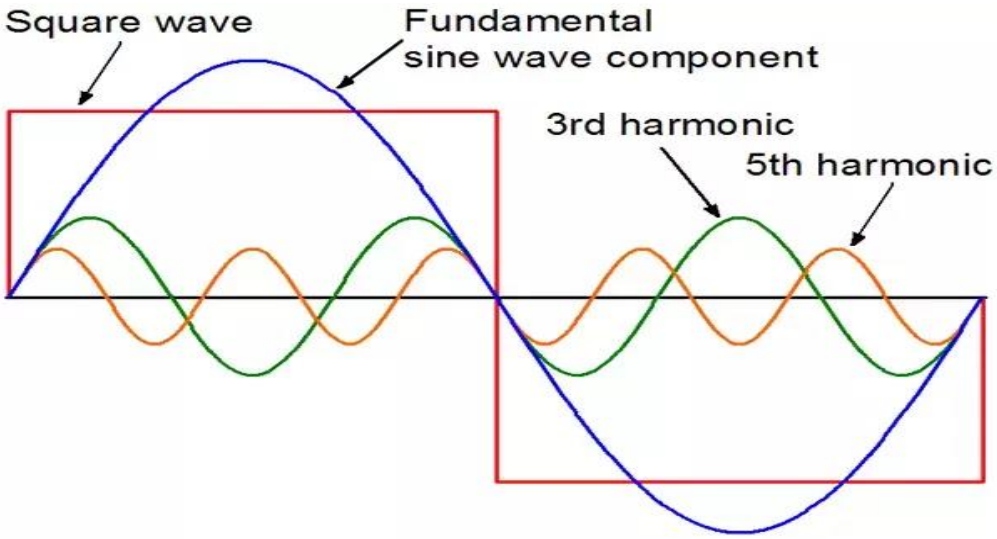

Figure 3: The Harmonics Formation for5th, 6th .7th and Total Harmonic.

Usually Both linear and non-linear loads are extensively used in every electrical load scenario. Throughout the applied voltage cycle, the impedance of a linear load stays constant. Resistive, inductive, and capacitive loads are examples of linear loads. In contrast, a non-linear load is defined as one whose impedance changes constantly with the applied voltage cycle. SMPS, electrical equipment, Selective catalytic reduction devices, UPS systems, and other non-linear devices are examples.

Harmonics, on the other hand, are distortions of a normal electrical current waveform that are often transmitted via non-linear loads that draw a sub sinusoidal signal from a sine voltage source. Harmonic current reduces efficiency and increases heat losses in the power system. Harmonic currents have the potential to cause significant damage to electrical distribution networks and the facilities they service.

Switch-mode power supplies (SMPS), variable-speed actuators and drives, copy machines, computers, LaserJet, fax machines, battery chargers, and UPSs are examples of nonlinear loads. Single-phase non-linear loads are prevalent in modern office buildings, while three-phase quasi loads are frequent in factories and industrial facilities. Harmonics are not to be confused with spikes, dips, surges, oscillation, or other kinds of hobos. Figure 4 depicts the harmonics generation for the 5th, 6th, and 7th harmonics, as well as the resulting fundamental sine wave component.

All computer systems need SMPSs for internal circuits, which convert utility AC power to regulated low-voltage DC. These non-linear power sources drain current in short, high-amplitude pulses, producing significant harmonic distortion in the electrical current and voltage waveforms (total harmonic distortion) (THD). The distortion is reflected back into the power source, putting other devices on the same supply at risk. Many power systems can tolerate a certain amount of harmonic current, but problems emerge when harmonics account for a significant portion of the overall load.

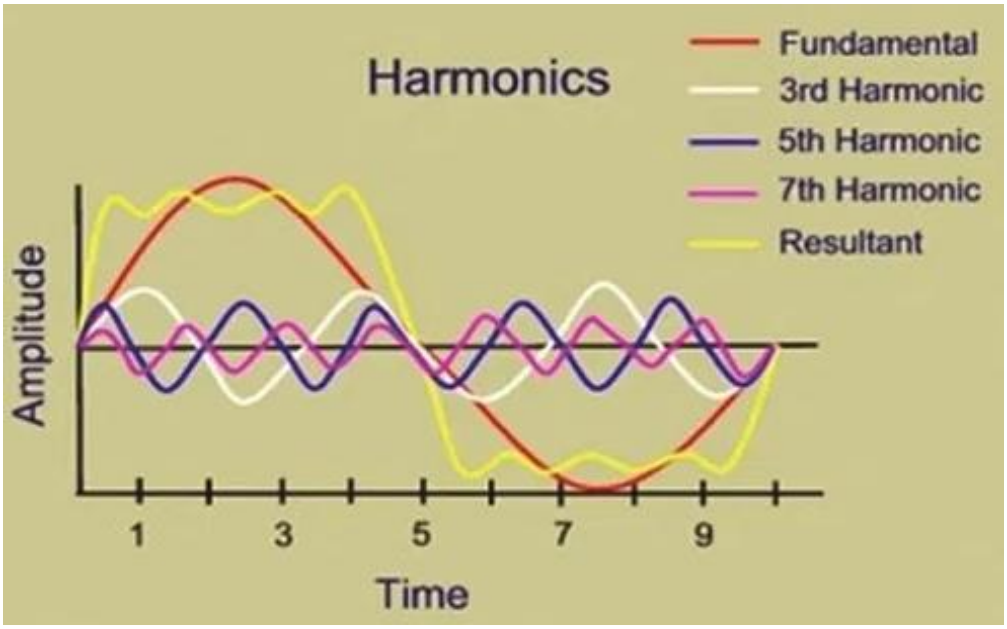

Figure 4:the Harmonics formation for the 5th, 6th .7th and Resultant Having Fundamental Sine Wave Component.

LITERATURE REVIEW
